SCO® UnixWare® is commercial computer software and, together with any related documentation, is subject to the restrictions on US Government use as set forth below. If this procurement is for a DOD agency, the following DFAR Restricted Rights Legend applies:

RESTRICTED RIGHTS LEGEND: Use, duplication, or disclosure by the Government is subject to restrictions as set forth in subparagraph (c)(1)(ii) of Rights in Technical Data and Computer Software Clause at DFARS 252.227-7013. Contractor / Manufacturer is The Santa Cruz Operation, Inc., 400 Encinal Street, Santa Cruz, CA 95060.

If this procurement is for a civilian government agency, this FAR Restricted Rights Legend applies:

RESTRICTED RIGHTS LEGEND: This computer software is submitted with restricted rights under Government Contract No. _____ (and Subcontract No. _____, if appropriate). It may not be used, reproduced, or disclosed by the Government except as provided in paragraph (g)(3)(i) of FAR Clause 52.227-14 alt III or as otherwise expressly stated in the contract. Contractor / Manufacturer is The Santa Cruz Operation, Inc., 400 Encinal Street, Santa Cruz, CA 95060.

If any copyrighted software accompanies this publication, it is licensed to the End User only for use in strict accordance with the End User License Agreement, which should be read carefully before commencing use of the software.

ACKNOWLEDGEMENTS

"We acknowledge the contributions of the 88OPEN Consortium Ltd., portions of whose *System V ABI Implementation Guide for the M88000 Processor* and the *System V ABI M88000 Processor Networking Supplement* have been incorporated in this section of the ABI with permission."

1 INTRODUCTION

The Intel386 Architecture and the System V ABI 1-1

How to Use the Intel386 Architecture ABI Supplement 1-2
Evolution of the ABI Specification 1-2

DRAFT COPY
March 19, 1997
File: abi_386/Cchap1 (Delta 44.3)
386:adm.book:sum

The Intel386 Architecture and the System V ABI

The *System V Application Binary Interface*, or ABI, defines a system interface for compiled application programs. Its purpose is to establish a standard binary interface for application programs on systems that implement the interfaces defined in the *System V Interface Definition, Edition 4*. This includes systems that have implemented UnixWare® 2.0. M

This document is a supplement to the generic *System V ABI*, and it contains information specific to System V implementations built on the Intel386 processor architecture. Together, these two specifications, the generic *System V ABI* and the *Intel386 Architecture System V ABI Supplement* (hereafter referred to as the *Intel386 ABI*), constitute a complete *System V Application Binary Interface* specification for systems that implement the processor architecture of the Intel386 microprocessors.

Note that, because the Intel486 and Pentium processor are compatible members of the Intel386 architecture, this *Intel386 ABI* also applies to any system built with the Intel486 or the Pentium processor chips. M M

How to Use the Intel386 Architecture ABI Supplement

This document is a supplement to the generic *System V ABI* and contains information referenced in the generic specification that may differ when System V is implemented on different processors. Therefore, the generic ABI is the prime reference document, and this supplement is provided to fill gaps in that specification.

As with the *System V ABI*, this specification references other publicly-available reference documents, especially the Intel *80386 Programmer's Reference Manual*. All the information referenced by this supplement should be considered part of this specification, and just as binding as the requirements and data explicitly included here.

Evolution of the ABI Specification

The *System V Application Binary Interface* will evolve over time to address new technology and market requirements, and will be reissued at intervals of approximately three years. Each new edition of the specification is likely to contain extensions and additions that will increase the potential capabilities of applications that are written to conform to the ABI.

As with the *System V Interface Definition*, the ABI will implement **Level 1** and **Level 2** support for its constituent parts. **Level 1** support indicates that a portion of the specification will continue to be supported indefinitely, while **Level 2** support means that a portion of the specification may be withdrawn or altered after the next edition of the ABI is made available. That is, a portion of the specification moved to **Level 2** support in an edition of the ABI specification will remain in effect at least until the following edition of the specification is published.

These **Level 1** and **Level 2** classifications and qualifications apply to this Supplement, as well as to the generic specification. All components of the ABI and of this supplement have **Level 1** support unless they are explicitly labelled as **Level 2**.

The following documents may be of interest to the reader of this specification:

- *i486 MICROPROCESSOR Programmer's Reference Manual* (Intel Literature order number 240486)

- *80386 Programmer's Reference Manual* (Intel Literature order number 230985)
- *80387 Programmer's Reference Manual* (Intel Literature order number 231917)
- *UnixWare® 2.0 Command Reference (a-l)*
- *UnixWare® 2.0 Command Reference (m-z)*
- *UnixWare® 2.0 Operating System API Reference: System Calls*
- *UnixWare® 2.0 Operating System API Reference: Library Functions*
- *UnixWare® 2.0 System Administration: Volumes I and II*
- *System V Interface Definition, Edition 4*

NOTE

Diffmarkings have been retained in the text of this book to indicate in which revisions of System V certain modifications were made to the *ABI*.

A "G" character in the right hand margin indicates a change in the *ABI* made in UNIX System V Release 4.2.

A "M" character in the right hand margin indicates a change in the *ABI* made in UnixWare® 2.0. M

2 SOFTWARE INSTALLATION

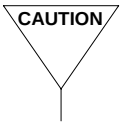

Software Distribution Formats 2-1
Physical Distribution Media 2-1
File System Formats 2-1
- s5 File System 2-1
- UFS File System 2-3

Software Distribution Formats

Physical Distribution Media

Approved media for physical distribution of ABI-conforming software are listed below. Inclusion of a particular medium on this list does not require an ABI-conforming system to accept that medium. For example, a conforming system may install all software through its network connection and accept none of the listed media.

- 1.44MB 3 1/2" floppy disk: quad-density, double-sided, 80 tracks/side, 18 sectors/track, 512 bytes/sector.
- 1.2MB 5 1/4" floppy disk: quad-density, double-sided, 80 tracks/side, 15 sectors/track, 512 bytes/sector.
- 360KB 5 1/4" floppy disk: double-density, double-sided, 40 tracks/side, 9 sectors/track, 512 bytes/sector.
- 60 MB quarter-inch cartridge tape in QIC-24 format. G
- CD-ROM optical disks. G
- 150 MB quarter-inch tape.

The use of 360KB 5 1/4" floppy disk, and 60 MB quarter inch cartridge tape as media for application distribution is moved to Level 2 as of January 1, 1993. G

File System Formats

Every file system storage volume must conform to a supported format. Two formats are supported: s5 and ufs.

s5 File System

The first physical block on the medium should be empty, and the second contains the device's *superblock*. The third contains an inode list, and remaining blocks on the device contain data. The *superblock* has the following format:

```
#define NICFREE             50
#define NICINOD             100

struct filsys {
         u_short   s_isize;
         daddr_t   s_fsize;
         short             s_nfree;
         daddr_t   s_free[NICFREE];
         short             s_ninode;
         ushort_t  s_inode[NICINOD];
         char              s_flock;
         char              s_ilock;
         char              s_fmod;
         char              s_ronly;
         time_t            s_time;
         short             s_dinfo[4];
         daddr_t   s_tfree;
         ushort_t  s_tinode;
         char              s_fname[6];
         char              s_fpack[6];
         long              s_fill[12];
         long              s_state;
         long              s_magic;
         long              s_type;
};

#define FsMAGIC    0xfd187e20

#define Fs1b               1
#define Fs2b               2
#define Fs4b               3

#define FsOKAY     0x7c269d38
#define FsACTIVE   0x5e72d81a
#define FsBAD              0xcb096f43
#define FsBADBLK   0xbadbc14b
```

s_type indicates the file system type. Currently, three types of file systems are supported: the original 512-byte logical block, the 1024-byte logical block, and the 2048-byte logical block. *s_magic* is used to distinguish the original 512-byte oriented file systems from the newer file systems. If this field is not equal to the magic number, `fsMAGIC`, the type is assumed to be `fs1b`, otherwise the *s_type* field is used.

s_state indicates the state of the file system. A cleanly unmounted, undamaged file system is indicated by the `FsOKAY` state. After a file system has been mounted for update, the state changes to `FsACTIVE`.

s_isize is the address of the first data block after the i-list; the i-list starts just after the super-block, namely in block 2; thus the i-list is *s_isize*–2 blocks long.

s_fsize is the first block not potentially available for allocation to a file.

The free list for each volume is maintained as follows. The *s_free* array contains up to 49 numbers of free blocks. *s_free*[0] is the block number of the head of a chain of blocks constituting the free list. The first long in each free-chain block is the number (up to 50) of free-block numbers listed in the next 50 longs of this chain member. The first of these 50 blocks is the link to the next member of the chain.

s_tfree is the total free blocks available in the file system.

s_ninode is the number of free i-numbers in the *s_inode* array.

s_tinode is the total free i-nodes available in the file system.

s_flock and *s_ilock* are flags maintained in the core copy of the file system. *s_fmod* is a flag that indicates that the super-block has changed and should be copied to the disk during the next periodic update of file system information.

s_ronly is a read-only flag to indicate write-protection.

s_time is the last time the super-block of the file system was changed, and is the number of seconds that have elapsed since 00:00 Jan. 1, 1970 (GMT).

s_fname is the name of the file system and *s_fpack* is the name of the pack.

I-numbers begin at 1, and the storage for i-nodes begins in block 2. I-node 1 is reserved for future use. I-node 2 is reserved for the root directory of the file system, but no other i-number has a built-in meaning. Each i-node represents one file.

UFS File System

In the UFS file system, the first physical block on the device should be empty, and the second contains the *superblock* for the file system. Remaining blocks contain data.

The ufs *superblock* contains an *fs* data structure. This structure, and other relevant data objects are defined below.

```
struct csum {
         long          cs_ndir;
         long          cs_nbfree;
         long          cs_nifree;
         long          cs_nffree;
};

struct fs {
         struct fs     *fs_link;
         struct fs     *fs_rlink;
         daddr_t       fs_sblkno;
         daddr_t       fs_cblkno;
         daddr_t       fs_iblkno;
         daddr_t       fs_dblkno;
         long          fs_cgoffset;
         long          fs_cgmask;
         time_t        fs_time;
         long          fs_size;
         long          fs_dsize;
         long          fs_ncg;
         long          fs_bsize;
         long          fs_fsize;
         long          fs_frag;
         long          fs_minfree;
         long          fs_rotdelay;
         long          fs_rps;
         long          fs_bmask;

Processor Architecture

The Intel *80386 Programmer's Reference Manual* (Intel Literature order number 230985) and the Intel *80387 Programmer's Reference Manual* (Intel Literature order number 231917) together define the processor architecture. The architecture of the combined Intel386/Intel 387 processors is hereafter referred to as the Intel386 architecture. Programs intended to execute directly on the processor use the instruction set, instruction encodings, and instruction semantics of the architecture. Three points deserve explicit mention.

- A program may assume all documented instructions exist.
- A program may assume all documented instructions work.
- A program may use only the instructions defined by the architecture.

In other words, *from a program's perspective*, the execution environment provides a complete and working implementation of the Intel386 architecture.

This does not imply that the underlying implementation provides all instructions in hardware, only that the instructions perform the specified operations and produce the specified results. The ABI neither places performance constraints on systems nor specifies what instructions must be implemented in hardware. A software emulation of the architecture could conform to the ABI.

Some processors might support the Intel386 architecture as a subset, providing additional instructions or capabilities. Programs that use those capabilities explicitly do not conform to the Intel386 ABI. Executing those programs on machines without the additional capabilities gives undefined behavior.

Data Representation

Within this specification, the term *halfword* refers to a 16-bit object, the term *word* refers to a 32-bit object, and the term *doubleword* refers to a 64-bit object.

Fundamental Types

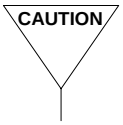

Figure 3-1 shows the correspondence between ANSI C's scalar types and the processor's.

Figure 3-1: Scalar Types

Type	C	sizeof	Alignment (bytes)	Intel386 Architecture
Integral	`char` `signed char`	1	1	signed byte
	`unsigned char`	1	1	unsigned byte
	`short` `signed short`	2	2	signed halfword
	`unsigned short`	2	2	unsigned halfword
	`int` `signed int` `long` `signed long` `enum`	4	4	signed word
	`unsigned int` `unsigned long`	4	4	unsigned word
Pointer	*any-type* `*` *any-type* `(*)()`	4	4	unsigned word
Floating-point	`float`	4	4	single-precision (IEEE)
	`double`	8	4	double-precision (IEEE)
	`long double`	12	4	extended-precision (IEEE)

NOTE

The Intel386 architecture does not require doubleword alignment for double-precision values. Nevertheless, for data structure compatibility with other Intel architectures, compilers may provide a method to align double-precision values on doubleword boundaries.

A compiler that provides the doubleword alignment mentioned above can generate code (data structures and function calling sequences) that do not conform to the Intel386 ABI. Programs built with the doubleword alignment facility can thus violate conformance to the Intel386 ABI. See ''Aggregates and Unions'' below and ''Function Calling Sequence'' later in this chapter for more information.

A null pointer (for all types) has the value zero.

The Intel386 architecture does not require all data access to be properly aligned. For example, double-precision values occupy 1 doubleword (8-bytes), and their natural alignment is a word boundary, meaning their addresses are multiples of 4. Compilers should allocate independent data objects with the proper alignment; examples include global arrays of double-precision variables, FORTRAN `COMMON` blocks, and unconstrained stack objects. However, some language facilities (such as FORTRAN `EQUIVALENCE` statements) may create objects with only byte alignment. Consequently, arbitrary data accesses, such as pointers dereference or reference arguments, might or might not be properly aligned. Accessing misaligned data will be slower than accessing properly aligned data, but otherwise there is no difference.

Aggregates and Unions

Aggregates (structures and arrays) and unions assume the alignment of their most strictly aligned component. The size of any object, including aggregates and unions, is always a multiple of the object's alignment. An array uses the same alignment as its elements. Structure and union objects can require padding to meet size and alignment constraints. The contents of any padding is undefined. G

- An entire structure or union object is aligned on the same boundary as its most strictly aligned member.
- Each member is assigned to the lowest available offset with the appropriate alignment. This may require *internal padding*, depending on the previous member.
- A structure's size is increased, if necessary, to make it a multiple of the alignment. This may require *tail padding*, depending on the last member.

NOTE

ABI conformant code may not read or modify anything marked reserved or padding. M

In the following examples, members' byte offsets appear in the upper right corners.

Figure 3-2: Structure Smaller Than a Word

```
struct {
    char   c;
};
```

Byte aligned, `sizeof` is 1

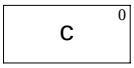

Figure 3-3: No Padding

```
struct {
    char   c;
    char   d;
    short  s;
    long   n;
};
```

Word aligned, `sizeof` is 8

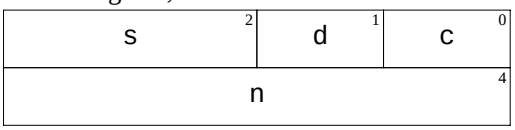

Figure 3-4: Internal Padding

```
struct {
    char   c;
    short  s;
};
```

Halfword aligned, `sizeof` is 4

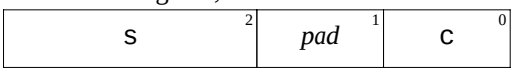

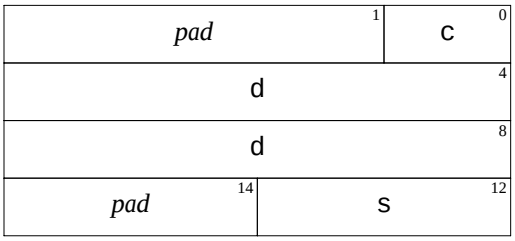

Figure 3-5: Internal and Tail Padding

```
struct {
    char   c;
    double d;
    short  s;
};
```

Word aligned, `sizeof` is 16

NOTE

The Intel386 architecture does not require doubleword alignment for double-precision values. Nevertheless, for data structure compatibility with other Intel architectures, compilers may provide a method to align double-precision values on doubleword boundaries.

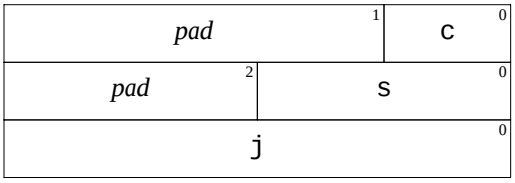

CAUTION

A compiler that provides the doubleword alignment mentioned above would arrange the preceding structure differently. Programs built with the double-word alignment facility would not conform to the Intel386 ABI, and they would not be data-compatible with conforming Intel386 programs.

Figure 3-6: `union` **Allocation**

```
union {
    char   c;
    short  s;
    int    j;
};
```

Word aligned, `sizeof` is 4

Bit-Fields

C `struct` and `union` definitions may have *bit-fields*, which define integral objects with a specified number of bits.

Figure 3-7: Bit-Field Ranges

Bit-field Type	Width *w*	Range
`signed char`	1 to 8	-2^{w-1} to $2^{w-1}-1$
`char`		0 to $2^{w}-1$
`unsigned char`		0 to $2^{w}-1$
`signed short`	1 to 16	-2^{w-1} to $2^{w-1}-1$
`short`		0 to $2^{w}-1$
`unsigned short`		0 to $2^{w}-1$
`signed int`	1 to 32	-2^{w-1} to $2^{w-1}-1$
`int`		0 to $2^{w}-1$
`enum`		0 to $2^{w}-1$
`unsigned int`		0 to $2^{w}-1$
`signed long`	1 to 32	-2^{w-1} to $2^{w-1}-1$
`long`		0 to $2^{w}-1$
`unsigned long`		0 to $2^{w}-1$

''Plain'' bit-fields (that is, those neither `signed` nor `unsigned`) always have non-negative values. Although they may have type `char`, `short`, `int`, or `long` (which can have negative values), these bit-fields have the same range as a bit-field of the same size with the corresponding `unsigned` type. Bit-fields obey the same size and alignment rules as other structure and union members, with the following additions:

- Bit-fields are allocated from right to left (least to most significant).
- A bit-field must entirely reside in a storage unit appropriate for its declared type. Thus a bit-field never crosses its unit boundary.
- Bit-fields may share a storage unit with other `struct/union` members, including members that are not bit-fields. Of course, `struct` members occupy different parts of the storage unit.
- Unnamed bit-fields' types do not affect the alignment of a structure or union, although individual bit-fields' member offsets obey the alignment constraints.

The following examples show `struct` and `union` members' byte offsets in the upper right corners; bit numbers appear in the lower corners.

Figure 3-8: Bit Numbering

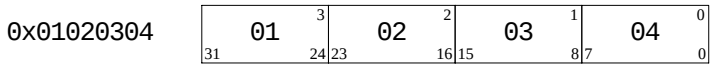

Figure 3-9: Right-to-Left Allocation

```
struct {
    int    j:5;
    int    k:6;
    int    m:7;
};
```

Word aligned, `sizeof` is 4

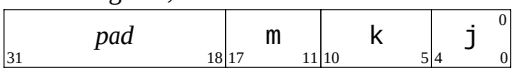

Figure 3-10: Boundary Alignment

```
struct {
    short  s:9;
    int    j:9;
    char   c;
    short  t:9;
    short  u:9;
    char   d;
};
```

Word aligned, `sizeof` is 12

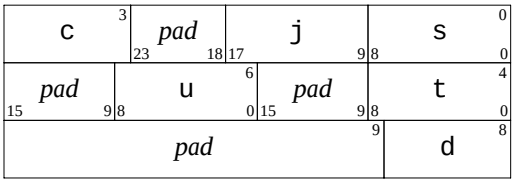

Figure 3-11: Storage Unit Sharing

```
struct {
    char   c;
    short  s:8;
};
```

Halfword aligned, `sizeof` is 2

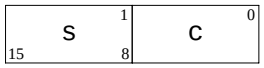

Figure 3-12: `union` **Allocation**

```
union {
    char   c;
    short  s:8;
};
```

Halfword aligned, `sizeof` is 2

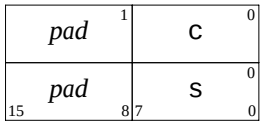

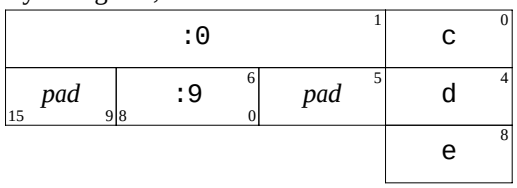

Figure 3-13: Unnamed Bit-Fields

```
struct {
    char   c;
    int    :0;
    char   d;
    short  :9;
    char   e;
    char   :0;
};
```

Byte aligned, `sizeof` is 9

As the examples show, `int` bit-fields (including `signed` and `unsigned`) pack more densely than smaller base types. One can use `char` and `short` bit-fields to force particular alignments, but `int` is generally more efficient.

Function Calling Sequence

This section discusses the standard function calling sequence, including stack frame layout, register usage, parameter passing, and so on. The system libraries described in Chapter 6 require this calling sequence.

NOTE

The standard calling sequence *requirements* apply only to global functions. Local functions that are not reachable from other compilation units may use different conventions. Nonetheless, it is recommended that all functions use the standard calling sequence when possible.

NOTE

C programs follow the conventions given here. For specific information on the implementation of C, see ‘‘Coding Examples’’ in this chapter.

Registers and the Stack Frame

The Intel386 architecture provides a number of registers. All the integer registers and all the floating-point registers are global to all procedures in a running program.

Brief register descriptions appear in Figure 3-14 more complete information appears later.

Figure 3-14: Processor Registers

Type	Name	Usage
General	%eax	Return value
	%edx	Dividend register (divide operations)
	%ecx	Count register (shift and string operations)
	%ebx	Local register variable
	%ebp	Stack frame pointer (optional) G
	%esi	Local register variable
	%edi	Local register variable
	%esp	Stack pointer
Floating-point	%st(0)	floating-point stack top, return value
	%st(1)	floating-point next to stack top
	. . .	
	%st(7)	floating-point stack bottom

In addition to registers, each function has a frame on the run-time stack. This stack grows downward from high addresses. Figure 3-15 shows the stack frame organization.

Figure 3-15: Standard Stack Frame

Position	Contents	Frame	
4*n*+8(%ebp)	argument word *n*	Previous	*High addresses*
	. . .		
8(%ebp)	argument word 0		
4(%ebp)	return address	Current	
0(%ebp)	previous %ebp (optional)		
-4(%ebp)	unspecified		
	. . .		
0(%esp)	variable size		*Low addresses*

Several key points about the stack frame deserve mention.

- The stack is word aligned. Although the architecture does not require any alignment of the stack, software convention and the operating system requires that the stack be aligned on a word boundary. G G

- Argument words are pushed onto the stack in reverse order (that is, the rightmost argument in C call syntax has the highest address), preserving the stack's word alignment. All incoming arguments appear on the stack, residing in the stack frame of the caller.
- An argument's size is increased, if necessary, to make it a multiple of words. This may require tail padding, depending on the size of the argument.
- Other areas depend on the compiler and the code being compiled. The standard calling sequence does not define a maximum stack frame size, nor does it restrict how a language system uses the ''unspecified'' area of the standard stack frame.

All registers on the Intel386 are global and thus visible to both a calling and a called function. Registers %ebp, %ebx, %edi, %esi, and %esp ''belong'' to the calling function. In other words, a called function must preserve these registers' values for its caller. Remaining registers ''belong'' to the called function. If a calling function wants to preserve such a register value across a function call, it must save the value in its local stack frame.

Some registers have assigned roles in the standard calling sequence:

%esp	The *stack pointer* holds the limit of the current stack frame, which is the address of the stack's bottom-most, valid word. At all times, the stack pointer should point to a word-aligned area.
%ebp	The *frame pointer* optionally holds a base address for the current stack frame. Consequently, a function has registers pointing to both ends of its frame. Incoming arguments reside in the previous frame, referenced as positive offsets from %ebp, while local variables reside in the current frame, referenced as negative offsets from %ebp. A function must preserve this register's value for its caller. G
%eax	*Integral and pointer return values* appear in %eax. A function that returns a `struct` or `union` value places the address of the result in %eax. Otherwise this is a scratch register.
%ebx	As described below, this register serves as the *global offset table base register* for position-independent code. For absolute code, %ebx serves as a local register and has no specified role in the function calling sequence. In either case, a function must preserve the register value for the caller.
%esi and %edi	These *local registers* have no specified role in the function calling sequence. A function must preserve their values for the caller.

%ecx and %edx
: *Scratch registers* have no specified role in the standard calling sequence. Functions do not have to preserve their values for the caller.

%st(0)
: *Floating-point return values* appear on the top of the floating-point register stack; there is no difference in the representation of single- or double-precision values in floating-point registers. If the function does not return a floating-point value, then this register must be empty. This register must be empty before entry to a function. G

%st(1) through %st(7)
: *Floating-point scratch registers* have no specified role in the standard calling sequence. These registers must be empty before entry and upon exit from a function.

EFLAGS
: The *flags register* contains the system flags, such as the direction flag and the carry flag. The direction flag must be set to the ''forward'' (that is, zero) direction before entry and upon exit from a function. Other user flags have no specified role in the standard calling sequence and are not preserved.

Floating-Point Control Word
: The Intel387 *control word* contains the floating-point flags, such as the rounding mode and exception masking. *

Signals can interrupt processes [see signal(BA_OS)]. Functions called during signal handling have no unusual restrictions on their use of registers. Moreover, if a signal handling function returns, the process resumes its original execution path with registers restored to their original values. Thus, programs and compilers may freely use all registers without the danger of signal handlers changing their values.

Functions Returning Scalars or No Value

A function that returns an integral or pointer value places its result in register %eax.

A floating-point return value appears on the top of the Intel387 register stack. The caller then must remove the value from the Intel387 stack, even if it doesn't use the value. Failure of either side to meet its obligations leads to undefined program behavior. The standard calling sequence does not include any method to detect such failures nor to detect return value type mismatches. Therefore the user must declare all functions properly. There is no difference in the representation of

single-, double- or extended-precision values in floating-point registers.

Functions that return no value (also called procedures or `void` functions) put no particular value in any register.

A `call` instruction pushes the address of the next instruction (the return address) onto the stack. The `ret` instruction pops the address off the stack and effectively continues execution at the next instruction after the `call` instruction. A function that returns a scalar or no value must preserve the caller's registers as described earlier. Additionally, the called function must remove the return address from the stack, leaving the stack pointer (`%esp`) with the value it had before the `call` instruction was executed.

To illustrate, the following function prologue allocates 80 bytes of local stack space and saves the local registers `%ebx`, `%esi`, and `%edi`.

Figure 3-16: Function Prologue

```
prologue:
        pushl  %ebp          / save frame pointer
        movl   %esp, %ebp    / set new frame pointer
        subl   $80, %esp     / allocate stack space
        pushl  %edi          / save local register
        pushl  %esi          / save local register
        pushl  %ebx          / save local register
```

An epilogue for the example that restores the state for the caller. This example returns the value in `%edi` by moving it to `%eax`.

Figure 3-17: Function Epilogue

```
        movl   %edi, %eax    / set up return value
epilogue:
        popl   %ebx          / restore local register
        popl   %esi          / restore local register
        popl   %edi          / restore local register
        leave                / restore frame pointer
        ret                  / pop return address
```

NOTE Although some functions can be optimized to eliminate the save and restore of the frame pointer, the general case uses the standard prologue and epilogue.

Sections below describe where arguments appear on the stack. The examples are written as if the function prologue described above had been used.

Position-independent code uses the %ebx register to hold the address of the global offset table. If a function needs the global offset table's address, either directly or indirectly, it is responsible for computing the value. See ''Coding Examples'' later in this chapter and ''Dynamic Linking'' in Chapter 5 for more information.

Functions Returning Structures or Unions

If a function returns a structure or union, then the caller provides space for the return value and places its address on the stack as argument word zero. In effect, this address becomes a ''hidden'' first argument. Having the caller supply the return object's space allows re-entrancy.

NOTE Structures and unions in this context have fixed sizes. The ABI does not specify how to handle variable sized objects.

DRAFT COPY
March 19, 1997
File: abi_386/chap3 (Delta 44.6)
386:adm.book:sum

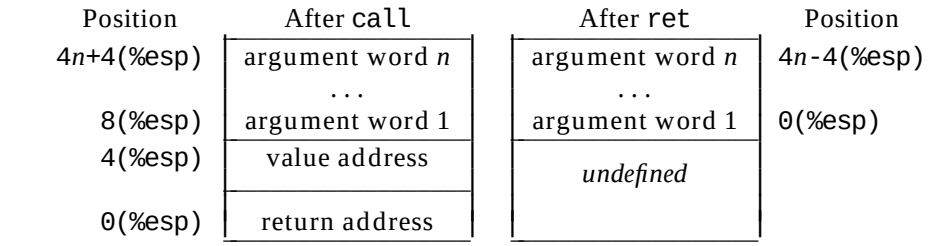

A function that returns a structure or union also sets %eax to the value of the original address of the caller's area before it returns. Thus when the caller receives control again, the address of the returned object resides in register %eax and can be used to access the object. Both the calling and the called functions must cooperate to pass the return value successfully:

- The calling function must supply space for the return value and pass its address in the stack frame;
- The called function must use the address from the frame and copy the return value to the object so supplied;
- The called function must remove this address from the stack before returning.

Failure of either side to meet its obligations leads to undefined program behavior. The standard function calling sequence does not include any method to detect such failures nor to detect structure and union type mismatches. Therefore the user must declare all functions properly.

Figure 3-18 illustrates the stack contents when the function receives control (after the call instruction) and when the calling function again receives control (after the ret instruction).

Figure 3-18: Stack Contents for Functions Returning struct/union

To illustrate, the following function prologue allocates 80 bytes of local stack space and saves the local registers %ebx, %esi, and %edi. Additionally, it removes the ''hidden'' argument from the stack and saves it in the highest word of the local stack frame.

Figure 3-19: Function Prologue (Returning `struct/union`)

```
prologue:
        popl   %eax           / pop return address
        xchgl  %eax, 0(%esp)  / swap return address
                                / and return value address
        pushl  %ebp           / save frame pointer
        movl   %esp, %ebp     / set new frame pointer
        subl   $80, %esp      / allocate local space
        pushl  %edi           / save local register
        pushl  %esi           / save local register
        pushl  %ebx           / save local register
        movl   %eax, -4(%ebp) / save return value address
```

An epilogue for the example that restores the state for the caller.

Figure 3-20: Function Epilogue

```
epilogue:
        movl   -4(%ebp), %eax     / set up return value
        popl   %ebx               / restore local register
        popl   %esi               / restore local register
        popl   %edi               / restore local register
        leave                     / restore frame pointer
        ret                       / pop return address
```

NOTE Although some functions can be optimized to eliminate the save and restore of the frame pointer, the general case uses the standard prologue and epilogue.

Sections below describe where arguments appear on the stack. The examples are written as if the function prologue described above had been used.

Position-independent code uses the `%ebx` register to hold the address of the global offset table. If a function needs the global offset table's address, either directly or indirectly, it is responsible for computing the value. See ''Coding Examples'' later in this chapter and ''Dynamic Linking'' in Chapter 5 for more information.

Integral and Pointer Arguments

As mentioned, a function receives all its arguments through the stack; the last argument is pushed first. In the standard calling sequence, the first argument is at offset `8(%ebp)`, the second argument is at offset `12(%ebp)`, and so on. Functions pass all integer-valued arguments as words, expanding or padding signed or unsigned bytes and halfwords as needed.

Figure 3-21: Integral and Pointer Arguments

Call	Argument	Stack address
	1	8(%ebp)
g(1, 2, 3,	2	12(%ebp)
(void *)0);	3	16(%ebp)
	(void *)0	20(%ebp)

Floating-Point Arguments

The stack also holds floating-point arguments: single-precision values use one word, double-precision use two, and extended-precision use three. See ''Coding Examples'' for information about floating-point arguments and variable argument lists. The example below uses only double-precision arguments. Single- and extended-precision arguments behave as specified above.

Figure 3-22: Floating-Point Arguments

Call	Argument	Stack address
`h(1.414, 1, 2.998e10);`	word 0, `1.414`	`8(%ebp)`
	word 1, `1.414`	`12(%ebp)`
	`1`	`16(%ebp)`
	word 0, `2.998e10`	`20(%ebp)`
	word 1, `2.998e10`	`24(%ebp)`

NOTE

The Intel386 architecture does not require doubleword alignment for double-precision values. Nevertheless, for data structure compatibility with other Intel architectures, compilers may provide a method to align double-precision values on doubleword boundaries.

CAUTION

A compiler that provides the doubleword alignment mentioned above would have to maintain doubleword alignment for the stack. Moreover, the arguments in the preceding example would appear in different positions. Programs built with the doubleword alignment facility would not conform to the Intel386 ABI, and their function calling sequence would not be compatible with conforming Intel386 programs.

Structure and Union Arguments

As described in the data representation section, structures and unions can have byte, halfword, or word alignment, depending on the constituents. An argument's size is increased, if necessary, to make it a multiple of words. This may require tail padding, depending on the size of the argument. To ensure that data in the stack is properly aligned, the stack pointer should always point to a word boundary. Structure and union arguments are pushed onto the stack in the same manner as integral arguments, described above. This provides call-by-value semantics, letting the called function modify its arguments without affecting the calling function's object.

Figure 3-23: Structure and Union Arguments

Call	Argument	Callee
`i(1, s);`	`1`	`8(%ebp)`
	word 0, `s`	`12(%ebp)`
	word 1, `s`	`16(%ebp)`
	...	...

Operating System Interface

Virtual Address Space

Processes execute in a 32-bit virtual address space. Memory management translates virtual addresses to physical addresses, hiding physical addressing and letting a process run anywhere in the system's real memory. Processes typically begin with three logical segments, commonly called text, data, and stack. As Chapter 5 describes, dynamic linking creates more segments during execution, and a process can create additional segments for itself with system services.

Page Size

Memory is organized by pages, which are the system's smallest units of memory allocation. Page size can vary from one system to another, depending on the processor, memory management unit and system configuration. Processes may call `sysconf`(BA_OS) to determine the system's current page size. *

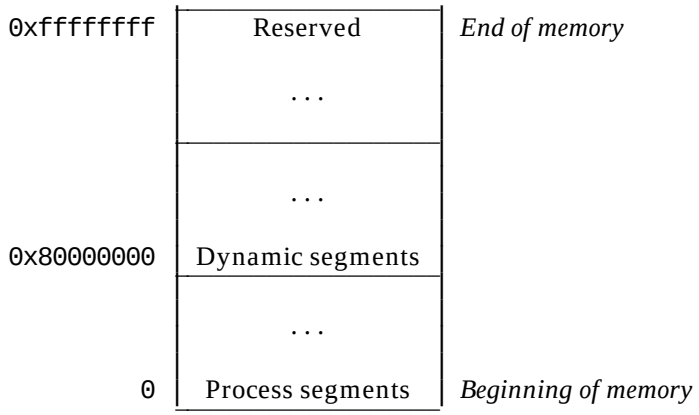

Virtual Address Assignments

Conceptually, processes have the full 32-bit address space available. In practice, however, several factors limit the size of a process.

- The system reserves a configuration-dependent amount of virtual space.
- The system reserves a configuration dependent amount of space per process. G
- A process whose size exceeds the system's available, combined physical memory and secondary storage cannot run. Although some physical memory must be present to run any process, the system can execute processes that are bigger than physical memory, paging them to and from secondary storage. Nonetheless, both physical memory and secondary storage are shared resources. System load, which can vary from one program execution to the next, affects the available amounts.

386:adm.book:sum

Figure 3-24: Virtual Address Configuration

CAUTION

Programs that dereference null pointers are erroneous. although an implementation is not obliged to detect such erroneous behavior. Such programs may or may not fail on a particular system. To enhance portability, programmers are strongly cautioned not to rely on this behavior. G G

Process segments

Processes' loadable segments and stack may begin at `0`. The exact addresses depend on the executable file format [see further information below and in Chapters 4 and 5]. Processes can control the amount of virtual memory allotted for stack space, as described below.

Dynamic segments

A process's dynamic segments reside below the reserved area.

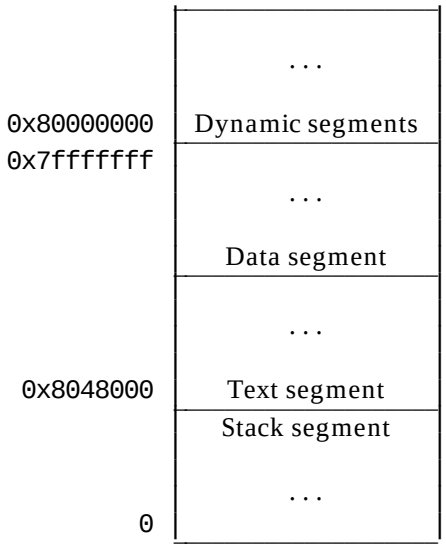

Reserved

A reserved area resides at the top of virtual space.

As the figure shows, the system reserves the high end of virtual address space, with a process's dynamic segments below that. Although the exact boundary between the reserved area and a process depends on the system's configuration, the reserved area shall not consume more than 1 GB of the address space. Thus the user virtual address range has a minimum upper bound of `0xc0000000`. Individual systems may reserve less space, increasing processes' virtual memory range.

Although applications may control their memory assignments, the typical arrangement appears below.

Figure 3-25: Conventional Segment Arrangements

The process's text segment resides at `0x8048000`. The data segment follows immediately, and dynamic segments occupy the higher range. When applications let the system choose addresses for dynamic segments (including shared object segments), it chooses high addresses. This leaves the ''middle'' of the address spectrum available for dynamic memory allocation with facilities such as `malloc`(BA_OS). Processes should *not* depend on finding their dynamic segments at particular virtual addresses. Facilities exist to let the system choose dynamic segment virtual addresses. The stack resides immediately below the text segment, growing toward lower addresses. This arrangement provides a little over 128 MB for the stack and about 2 GB for text and data.

Managing the Process Stack

Section ''Process Initialization'' in this chapter describes the initial stack contents. Stack addresses can change from one system to the next—even from one process execution to the next on the same system. Processes, therefore, should *not* depend on finding their stack at a particular virtual address.

A tunable configuration parameter controls the system maximum stack size. A process also can use `setrlimit`(BA_OS), to set its own maximum stack size, up to the system limit. On the Intel386, the stack segment has read and write permissions.

Coding Guidelines

Operating system facilities, such as `mmap`(KE_OS), allow a process to establish address mappings in two ways. First, the program can let the system choose an address. Second, the program can force the system to use an address the program supplies. This second alternative can cause application portability problems, because the requested address might not always be available. Differences in virtual address space can be particularly troublesome between different architectures, but the same problems can arise within a single architecture.

Processes' address spaces typically have three segment areas that can change size from one execution to the next: the stack [through `setrlimit`(BA_OS)], the data segment [through `malloc`(BA_OS)], and the dynamic segment area [through `mmap`(KE_OS)]. Changes in one area may affect the virtual addresses available for another. Consequently, an address that is available in one process execution might not be available in the next. A program that used `mmap`(KE_OS) to request a mapping at a specific address thus could appear to work in some environments and fail in others. For this reason, programs that wish to establish a mapping in their address space should let the system choose the address.

Despite these warnings about requesting specific addresses, the facility is both useful and can be used in a controlled manner. For example, a multiprocess application might map several files into the address space of each process and build relative pointers among the files' data. This could be done by having each process ask for a certain amount of memory at an address chosen by the system. After each process receives its own, private address from the system, it would map the desired files into memory, at specific addresses within the original area. This collection of mappings could be at different addresses in each process but their *relative* positions would be fixed. Without the ability to ask for specific addresses, the application could not build shared data structures, because the relative positions for files in each process would be unpredictable.

Processor Execution Modes

Four execution modes exist in the Intel386 architecture: ring 3 (or user mode) and three privileged rings. User processes run in user mode ring (the least privileged). The operating system kernel runs in a privileged mode ring, although the ABI does not specify which one. A program executes the `lcall` instruction through a system call gate to change execution modes, and thus the `lcall` instruction provides the low-level interface to system calls. For the Intel386, one low-level interface is defined: `_exit`(BA_OS).

To ensure a process has a way to terminate itself, the system treats `_exit` as a special case. The ABI does not specify the implementation of other system services. Instead, programs should use the system libraries that Chapter 6 describes. Programs with other embedded `lcall` instructions do not conform to the ABI.

Figure 3-26: `_exit` System Trap

```
        .globl _exit
_exit:
        movl   $1, %eax
        lcall  $7, $0
```

Exception Interface

As the Intel386 architecture manuals describe, the processor changes mode to handle *exceptions*, which may be synchronous, floating-point/coprocessor, or asynchronous. Synchronous and floating-point/coprocessor exceptions, being caused by instruction execution, can be explicitly generated by a process. This section, therefore, specifies those exception types with defined behavior. The Intel386 architecture classifies exceptions as *faults*, *traps*, and *aborts*. See the Intel *80386 Programmer's Reference Manual* for more information about their differences.

Hardware Exception Types

The operating system defines the following correspondence between hardware exceptions and the signals specified by `signal`(BA_OS).

Figure 3-27: Hardware Exceptions and Signals

Number	Exception Name	Signal
0	divide error fault	SIGFPE
1	single step trap / fault	SIGTRAP
2	nonmaskable interrupt	none
3	breakpoint trap	SIGTRAP
4	overflow trap	SIGSEGV
5	bounds check fault	SIGSEGV
6	invalid opcode fault	SIGILL
7	no coprocessor fault	SIGFPE
8	double fault abort	none
9	coprocessor overrun abort	SIGSEGV
10	invalid TSS fault	none
11	segment not present fault	none
12	stack exception fault	SIGSEGV
13	general protection fault / abort	SIGSEGV
14	page fault	SIGSEGV
15	(reserved)	
16	coprocessor error fault	SIGFPE
other	(unspecified)	SIGILL

Floating-point instructions exist in the architecture, but they may be implemented either in hardware (via the Intel387 chip) or in software (via the Intel387 emulator). In the case of ''no coprocessor'' exception, if the Intel387 emulator is configured into the kernel, the process receives no signal. Instead, the system intercepts the exception, emulates the instruction, and returns control to the process. A process receives SIGFPE for the ''no coprocessor'' exception only when the indicated floating-point instruction is illegal (invalid operands, and so on).

Software Trap Types

Because the `int` instruction generates traps, some hardware exceptions can be generated by software. However, the `int` instruction generates only traps and not faults; so it is not possible to match the exact hardware generated faults in software.

Process Initialization

This section describes the machine state that exec(BA_OS) creates for ''infant'' processes, including argument passing, register usage, stack frame layout, and so on. Programming language systems use this initial program state to establish a standard environment for their application programs. As an example, a C program begins executing at a function named main, conventionally declared in the following way.

Figure 3-28: Declaration for main

```
extern int main(int argc, char *argv[], char *envp[]);
```

Briefly, argc is a non-negative argument count; argv is an array of argument strings, with argv[argc]==0; and envp is an array of environment strings, also terminated by a null pointer.

Although this section does not describe C program initialization, it gives the information necessary to implement the call to main or to the entry point for a program in any other language.

Special Registers

As the Intel386 architecture defines, several state registers control and monitor the processor: the Machine Status Word register (MSW, also known as register %cr0), EFLAGS register, the floating-point status register, and the floating-point control register. Application programs cannot access the full EFLAGS register directly; because they run in the processor's *user mode*, and the instructions to write some of the bits of the EFLAGS register are privileged. Nonetheless, a program has access to many of the flags in the EFLAGS register. Flags identified with an ''*'' below are not modifiable by a user mode process, they either have unspecified values or do not affect user program behavior. At process initialization, the EFLAGS register contains the following values.

Figure 3-29: EFLAGS Register Fields

Flag	Value	Note
CF	unspecified	Carry flag
PF	unspecified	Parity flag
AF	unspecified	Auxiliary carry flag
ZF	unspecified	Zero flag
SF	unspecified	Sign flag
TF	unspecified	Trap flag
IF*	unspecified	Interrupt enable
DF	0	Direction flag low to high
OF	unspecified	Overflow flag
IOPL*	unspecified	I/O privilege level
NT*	unspecified	Nested task
RF*	unspecified	Resume flag
VM*	unspecified	Virtual 8086 mode

The Intel386 architecture defines floating-point instructions, and those instructions work whether the processor has a hardware floating-point unit or not. (A system may provide hardware or software floating-point facilities.) Consequently, the contents of the MSW register is not specified, letting the system set it according to the hardware configuration. In any case, however, the processor presents a working floating-point implementation, including the Intel387 status and control word registers with the following values at process initialization.

Figure 3-30: Floating-Point Control Word

Field	Value	Note	
IC	1	Affine infinity (for compatibility)	
RC	00	Round to nearest or even	
PC	11	53-bit (double precision)	G
PM	1	Precision masked	
UM	1	Underflow masked	
OM	1	Overflow	G
ZM	1	Zero divide	G
DM	1	Denormalized operand masked	
IM	1	Invalid operation	G

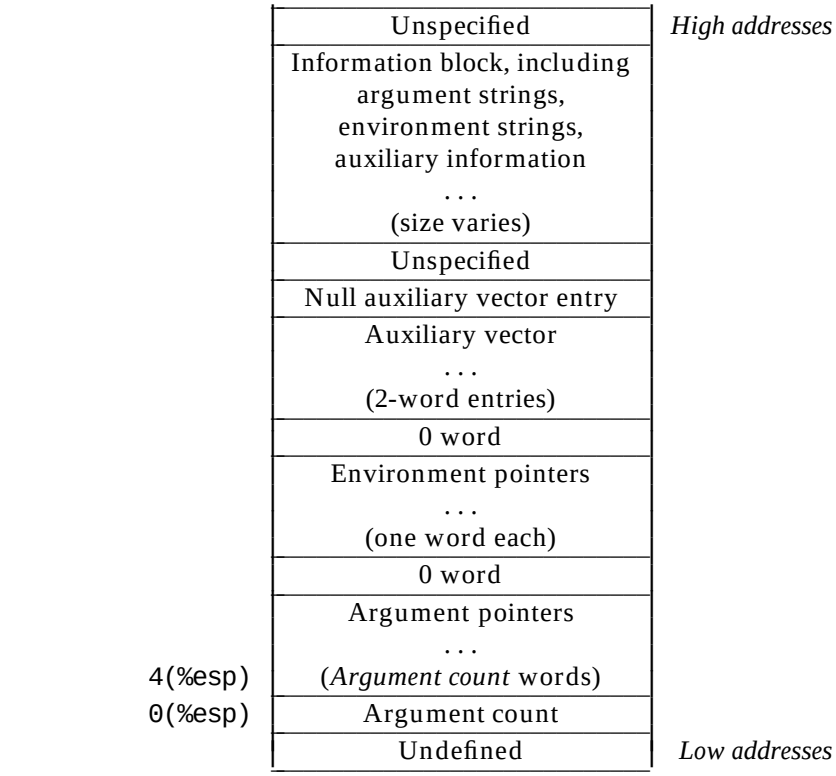

CAUTION

The initial floating-point state should be changed with care. In particular, many floating-point routines may produce undefined behavior if the precision control is set to less than 53 bits. The _fpstart routine (see Chapter 6) changes the precision control to 64 bits and sets all exceptions to be asked. This is the default state required for conformance to the ANSI C standard and to the IEEE 754 Floating-point standard. G G G G

Process Stack and Registers

When a process receives control, its stack holds the arguments and environment from exec(BA_OS).

Figure 3-31: Initial Process Stack

Argument strings, environment strings, and the auxiliary information appear in no specific order within the information block; the system makes no guarantees about their arrangement. The system also may leave an unspecified amount of memory between the null auxiliary vector entry and the beginning of the information block.

General and floating-point register values are unspecified at process entry, with the exceptions appearing below. Consequently, a program that requires registers to have specific values must set them explicitly during process initialization. It should *not* rely on the operating system to set all registers to 0.

`%ebp` The content of this register is unspecified at process initialization time, but the user code should mark the deepest stack frame by setting the frame pointer to zero. No other frame's `%ebp` should have a zero value.

`%esp` Performing its usual job, the stack pointer holds the address of the bottom of the stack, which is guaranteed to be word aligned.

`%edx` In a conforming program, this register contains a function pointer that the application should register with `atexit`(BA_OS). This function is used for shared object termination code [see ''Dynamic Linking'' in Chapter 5 of the *System V ABI*].

`%cs, %ds, %es, %ss`
The segment registers are initialized so that the user process can address the code, data, and stack segments using a 32-bit virtual address. A program that alters their values does not conform to the ABI and has undefined behavior.

Every process has a stack, but the system defines *no* fixed stack address. Furthermore, a program's stack address can change from one system to another—even from one process invocation to another. Thus the process initialization code must use the stack address in `%esp`. Data in the stack segment at addresses below the stack pointer contain undefined values.

Whereas the argument and environment vectors transmit information from one application program to another, the auxiliary vector conveys information from the operating system to the program. This vector is an array of the following structures, interpreted according to the `a_type` member.

Figure 3-32: Auxiliary Vector

```
typedef struct
{
      int    a_type;
      union {
            long   a_val;
            void   *a_ptr;
            void   (*a_fcn)();
      } a_un;
} auxv_t;
```

Figure 3-33: Auxiliary Vector Types, a_type

Name	Value	a_un	
AT_NULL	0	ignored	
AT_IGNORE	1	ignored	
AT_EXECFD	2	a_val	
AT_PHDR	3	a_ptr	
AT_PHENT	4	a_val	
AT_PHNUM	5	a_val	
AT_PAGESZ	6	a_val	
AT_BASE	7	a_ptr	
AT_FLAGS	8	a_val	
AT_ENTRY	9	a_ptr	
AT_LIBPATH	10	a_val	M
AT_FPHW	11	a_val	M
AT_INTP_DEVICE	12	a_val	M
AT_INTP_INODE	13	a_val	M

AT_NULL — The auxiliary vector has no fixed length; instead its last entry's a_type member has this value.

AT_IGNORE This type indicates the entry has no meaning. The corresponding value of a_un is undefined.

AT_EXECFD As Chapter 5 describes, exec(BA_OS) may pass control to an interpreter program. When this happens, the system places either an entry of type AT_EXECFD or one of type AT_PHDR in the auxiliary vector. The entry for type AT_EXECFD uses the a_val member to contain a file descriptor open to read the application program's object file.

AT_PHDR Under some conditions, the system creates the memory image of the application program before passing control to the interpreter program. When this happens, the a_ptr member of the AT_PHDR entry tells the interpreter where to find the program header table in the memory image. If the AT_PHDR entry is present, entries of types AT_PHENT, AT_PHNUM, and AT_ENTRY must also be present. See Chapter 5 in both the System V ABI and the processor supplement for more information about the program header table.

AT_PHENT The a_val member of this entry holds the size, in bytes, of one entry in the program header table to which the AT_PHDR entry points.

AT_PHNUM The a_val member of this entry holds the number of entries in the program header table to which the AT_PHDR entry points.

AT_PAGESZ If present, this entry's a_val member gives the system page size, in bytes. The same information also is available through sysconf(BA_OS).

AT_BASE The a_ptr member of this entry holds the base address at which the interpreter program was loaded into memory. See ''Program Header'' in the System V ABI for more information about the base address.

AT_FLAGS If present, the a_val member of this entry holds one-bit flags. Bits with undefined semantics are set to zero.

AT_ENTRY The a_ptr member of this entry holds the entry point of the application program to which the interpreter program should transfer control.

AT_LIBPATH The a_val member of this entry is non-zero if the dynamic linker should examine LD_LIBRARY_PATH when searching for shared objects of the process based on the security considerations in the Shared Object Dependency section in Chapter 5 of the gABI.

AT_FPHW The a_val member of this entry will be set to

Figure 3-34: AT_FPHW values

Value	Meaning
0	if no floating point support exists
1	if floating point software emulation exists
2	if it has a 80287 chip
3	if it has a 80387 chip or a 80487 chip

AT_INTP_DEVICE
The a_val member of this entry holds the device number of the file from which the dynamic linker is loaded.

AT_INTP_INODE
The a_val member of this entry holds the inode of the file from which the dynamic linker is loaded.

Other auxiliary vector types are reserved. No flags are currently defined for AT_FLAGS, on the Intel386 architecture.

To illustrate, suppose an example process receives two arguments.

- echo
- abi

It also inherits two environment strings (this example is not intended to show a fully configured execution environment).

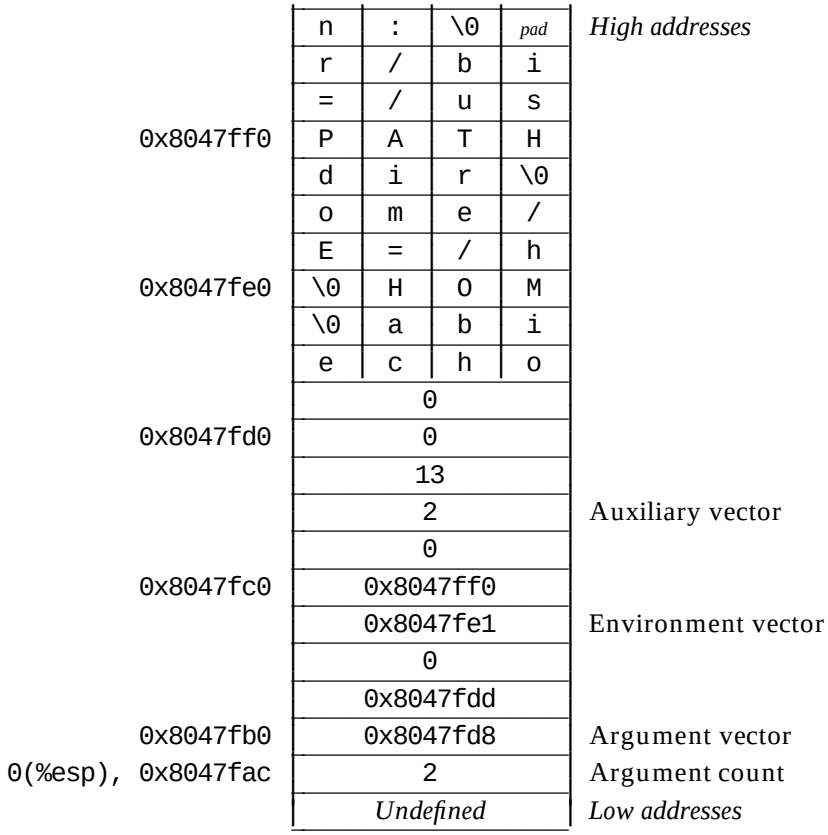

- HOME=/home/dir
- PATH=/usr/bin:

Its one non-null auxiliary vector entry holds a file descriptor.

- {AT_EXECFD, 13}

The resulting stack resides below 0x8048000, growing toward lower addresses.

Figure 3-35: Example Process Stack

Coding Examples

This section discusses example code sequences for fundamental operations such as calling functions, accessing static objects, and transferring control from one part of a program to another. Previous sections discuss how a program may use the machine or the operating system, and they specify what a program may and may not assume about the execution environment. Unlike previous material, the information here illustrates how operations *may* be done, not how they *must* be done.

As before, examples use the ANSI C language. Other programming languages may use the same conventions displayed below, but failure to do so does *not* prevent a program from conforming to the ABI. Two main object code models are available.

- *Absolute code*. Instructions can hold absolute addresses under this model. To execute properly, the program must be loaded at a specific virtual address, making the program's absolute addresses coincide with the process's virtual addresses.
- *Position-independent code*. Instructions under this model hold relative addresses, *not* absolute addresses. Consequently, the code is not tied to a specific load address, allowing it to execute properly at various positions in virtual memory.

Following sections describe the differences between these models. Code sequences for the models (when different) appear together, allowing easier comparison.

NOTE

Examples below show code fragments with various simplifications. They are intended to explain addressing modes, not to show optimal code sequences nor to reproduce compiler output.

NOTE

When other sections of this document show assembly language code sequences, they typically show only the absolute versions. Information in this section explains how position-independent code would alter the examples.

Code Model Overview

When the system creates a process image, the executable file portion of the process has fixed addresses, and the system chooses shared object library virtual addresses to avoid conflicts with other segments in the process. To maximize text sharing, shared objects conventionally use position-independent code, in which instructions contain no absolute addresses. Shared object text segments can be loaded at various virtual addresses without having to change the segment images. Thus multiple processes can share a single shared object text segment, even though the segment resides at a different virtual address in each process.

Position-independent code relies on two techniques.

- Control transfer instructions hold offsets relative to the extended instruction pointer (EIP). An EIP-relative branch or function call computes its destination address in terms of the current instruction pointer, *not* relative to any absolute address.
- When the program requires an absolute address, it computes the desired value. Instead of embedding absolute addresses in the instructions, the compiler generates code to calculate an absolute address during execution.

Because the Intel386 architecture provides EIP-relative call and branch instructions, compilers can satisfy the first condition easily.

A *global offset table* provides information for address calculation. Position-independent object files (executable and shared object files) have this table in their data segment. When the system creates the memory image for an object file, the table entries are relocated to reflect the absolute virtual addresses as assigned for an individual process. Because data segments are private for each process, the table entries can change—unlike text segments, which multiple processes share.

Assembly language examples below show the explicit notation needed for position-independent code.

name`@GOT(%ebx)`
: This expression denotes an `%ebx`-relative reference to the global offset table entry for the symbol *name*. The `%ebx` register contains the absolute address of the global offset table, as explained below.

name`@GOTOFF(%ebx)`
: This expression denotes an `%ebx`-relative reference to the symbol *name*. Again, `%ebx` holds the global offset table address. Note this expression references *name*, not the global offset table entry for *name*.

name@PLT This expression denotes an EIP-relative reference to the procedure linkage table entry for the symbol *name*.

_GLOBAL_OFFSET_TABLE_
The symbol _GLOBAL_OFFSET_TABLE_ is used to access the global offset table. When an instruction uses the symbol, it sees the offset between the current instruction and the global offset table as the symbol value.

Position-Independent Function Prologue

This section describes the function prologue for position-independent code. A function's prologue allocates the local stack space, saves any registers it must preserve, and sets register %ebx to the global offset table's address. Because %ebx is private for each function and preserved across function calls, a function calculates its value once at the entry.

Figure 3-36: Calculating Global Offset Table Address

```
Line                          Code
  1     call   .L1
  2  .L1:  popl   %ebx
  3        addl   $_GLOBAL_OFFSET_TABLE_+[.-.L1], %ebx
```

These three lines accomplish the following.

1. The call instruction pushes the *absolute* address of the next instruction onto the stack.
2. Consequently, the popl instruction pops the absolute address of .L1 into register %ebx.
3. The last instruction computes the desired absolute value into %ebx. This works because _GLOBAL_OFFSET_TABLE_ in the expression gives the distance from the addl instruction to the global offset table; [.-.L1] gives the distance from .L1 to the addl instruction. Adding their sum to the absolute address of .L1, already in %ebx, gives the absolute address of the global offset table.

This computation can be added to the standard function prologue, giving the standard prologue for position-independent code. To illustrate, the following function prologue allocates 80 bytes of local stack space and saves the local registers %ebx, %esi, and %edi.

Figure 3-37: Position-Independent Function Prologue

```
prologue:
        pushl  %ebp
        movl   %esp, %ebp
        subl   $80, %esp
        pushl  %edi
        pushl  %esi
        pushl  %ebx
        call   .L1
.L1:    popl   %ebx
        addl   $_GLOBAL_OFFSET_TABLE_+[.-.L1], %ebx
```

Position-independent and absolute code use the same function epilogue.

Data Objects

This discussion excludes stack-resident objects, because programs always compute their virtual addresses relative to the stack and frame pointers. Instead, this section describes objects with static storage duration.

In the Intel386 architecture, all memory reference instructions can address any location within the 32-bit address space. Symbolic references in absolute code put the symbols' values—or absolute virtual addresses—into instructions.

Figure 3-38: Absolute Data Access

C	Assembly
`extern int src;` `extern int dst;` `extern int *ptr;` `ptr = &dst;` `*ptr = src;`	`.globl  src, dst, ptr` `movl    $dst, ptr` `movl    ptr, %eax` `movl    src, %edx` `movl    %edx, (%eax)`

Position-independent instructions cannot contain absolute addresses. Instead, instructions that reference symbols hold the symbols' offsets into the global offset table. Combining the offset with the global offset table address in %ebx gives the absolute address of the table entry holding the desired address.

Figure 3-39: Position-Independent Data Access

C	Assembly
`extern int src;` `extern int dst;` `extern int *ptr;` `ptr = &dst;` `*ptr = src;`	`.globl  src, dst, ptr` `movl    ptr@GOT(%ebx), %eax` `movl    dst@GOT(%ebx), %edx` `movl    %edx, (%eax)` `movl    ptr@GOT(%ebx), %eax` `movl    (%eax), %eax` `movl    src@GOT(%ebx), %edx` `movl    (%edx), %edx` `movl    %edx, (%eax)`

Finally, position-independent references to static data may be optimized. Because %ebx holds a known address, the global offset table, a program may use it as a base register. External references should use the global offset table entry, because dynamic linking may bind the entry to a definition outside the current object file's scope.

Figure 3-40: Position-Independent Static Data Access

C

```
static int src;
static int dst;
static int *ptr;
ptr = &dst;

*ptr = src;
```

Assembly

```
leal   ptr@GOTOFF(%ebx), %eax
leal   dst@GOTOFF(%ebx), %edx
movl   %edx, (%eax)

movl   ptr@GOTOFF(%ebx), %eax
movl   src@GOTOFF(%ebx), %edx
movl   %edx, (%eax)
```

Function Calls

Programs use the `call` instruction to make direct function calls. A `call` instruction's destination is an EIP-relative value that can reach any address in the 32-bit virtual space. Even when the code for a function resides in a shared object, the caller uses the same assembly language instruction sequence, although in that case control passes from the original call, through an indirection sequence, to the desired destination. See ''Procedure Linkage Table'' in Chapter 5 for more information on the indirection sequence.

Figure 3-41: Absolute Direct Function Call

C

```
extern void function();
function();
```

Assembly

```
.globl   function
call     function
```

Dynamic linking may redirect a function call outside the current object file's scope; so position-independent calls should use the procedure linkage table explicitly.

Figure 3-42: Position-Independent Direct Function Call

C

```
extern void function();
function();
```

Assembly

```
.globl   function
call     function@PLT
```

Indirect function calls use the indirect `call` instruction.

Figure 3-43: Absolute Indirect Function Call

C

```
extern void (*ptr)();
extern void name();
ptr = name;

(*ptr)();
```

Assembly

```
.globl   ptr, name;

movl     $name, ptr

call     *ptr
```

For position-independent code, the global offset table supplies absolute addresses for all required symbols, whether the symbols name objects or functions.

Figure 3-44: Position-Independent Indirect Function Call

C

```
extern void (*ptr)();
extern void name();
ptr = name;

(*ptr)();
```

Assembly

```
.globl   ptr, name

movl     ptr@GOT(%ebx), %eax
movl     name@GOT(%ebx), %edx
movl     %edx, (%eax)

movl     ptr@GOT(%ebx), %eax
call     *(%eax)
```

Branching

Programs use branch instructions to control their execution flow. As defined by the Intel386 architecture, branch instructions hold an EIP-relative value with a signed 32-bit range, allowing a jump to any location within the virtual address space.

Figure 3-45: Branch Instruction, All Models

C

```
label:
        . . .
        goto label;
```

Assembly

```
.L01:
        . . .
        jmp     .L01
```

C `switch` statements provide multiway selection. When the `case` labels of a `switch` statement satisfy grouping constraints, the compiler implements the selection with an address table. The following examples use several simplifying conventions to hide irrelevant details:

- The selection expression resides in register `%eax;`
- `case` label constants begin at zero;
- `case` labels, `default`, and the address table use assembly names `.Lcase`*i*, `.Ldef`, and `.Ltab`, respectively.

Address table entries for absolute code contain virtual addresses; the selection code extracts an entry's value and jumps to that address. Position-independent table entries hold offsets; the selection code computes a destination's absolute address.

Figure 3-46: Absolute `switch` Code

C

```
switch (j)
{
case 0:
     . . .
case 2:
     . . .
case 3:
     . . .
default:
     . . .
}
```

Assembly

```
          cmpl    $3, %eax
          ja      .Ldef
          jmp     *.Ltab(,%eax,4)
.Ltab:    .long   .Lcase0
          .long   .Ldef
          .long   .Lcase2
          .long   .Lcase3
```

Figure 3-47: Position-Independent `switch` Code

C

```
switch (j)
{
case 0:
     . . .
case 2:
     . . .
case 3:
     . . .
default:
     . . .
}
```

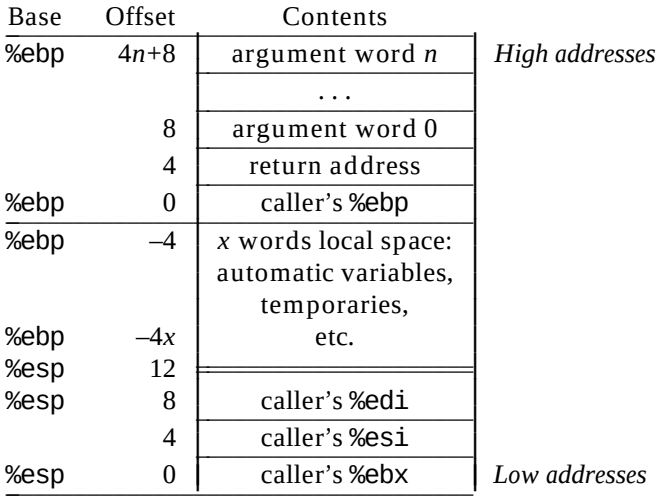

Assembly

```
     cmpl    $3, %eax
     ja      .Ldef
     leal    .Ltab@GOTOFF(%ebx), %edx
     movl    (%edx,%eax,4), %eax
     movl    .Ltab@GOTOFF(%ebx,%eax,4), %eax
     call    .Ljmp
.Ljmp:
     popl    %ecx
     addl    %ecx, %eax
     jmp     *%eax
.Ltab:
     .long   .Lcase0 - .Ljmp
     .long   .Ldef - .Ljmp
     .long   .Lcase2 - .Ljmp
     .long   .Lcase3 - .Ljmp
```

C Stack Frame

Figure 3-48 shows the C stack frame organization. It conforms to the standard stack frame with designated roles for unspecified areas in the standard frame. M
This represents one possible organization of the C stack frame. Usage of %ebp as a M
frame pointer, the exact positions of the callee saved registers, and space for local M
storage is implementation specific.

Figure 3-48: C Stack Frame

A C stack frame doesn't normally change size during execution. The exception is dynamically allocated stack memory, discussed below. By convention, a function allocates automatic (local) variables in the middle of its frame and references them as negative offsets from %ebp. Its incoming arguments reside in the previous frame, referenced as positive offsets from %ebp. If necessary, a function saves the values of %edi, %esi, and %ebx in the positions shown and restores their values before returning to the caller. The positions may be different from the diagram above, depending on which of these three registers the function saves and restores.

Variable Argument List

Previous sections describe the rules for passing arguments. Unfortunately, some otherwise portable C programs depend on the argument passing scheme, implicitly assuming that 1) all arguments reside on the stack, and 2) arguments appear in increasing order on the stack. Programs that make these assumptions never have been portable, but they have worked on many machines, including the Intel386. Nonetheless, portable C programs should use the facilities defined in the header files <stdarg.h> or <varargs.h> to deal with variable argument lists.

Allocating Stack Space Dynamically

Unlike some other languages, C does not need dynamic stack allocation *within* a stack frame. Frames are allocated dynamically on the program stack, depending on program execution, but individual stack frames can have static sizes. Nonetheless, the architecture supports dynamic allocation for those languages that require it, and the standard calling sequence and stack frame support it as well. Thus languages that need dynamic stack frame sizes can call C functions, and vice versa.

Figure 3-48 shows the layout of the C stack frame. The double line divides the area referenced from %ebp from the area referenced from %esp. Dynamic space is allocated below the line, as a downward growing heap whose size changes as required. Typical C functions have no space in the heap. All areas above the heap in the current frame have a known size to the compiler. Dynamic stack allocation thus takes the following steps.

1. Stack frames are word aligned; dynamic allocation should preserve this property. Thus the program rounds (up) the desired byte count to a multiple of 4.
2. The program decreases the stack pointer by the rounded byte count, increasing its frame size. At this point, the ‘‘new’’ space resides just below the register save area at the bottom of the stack.
3. The program copies the register save area (three or fewer words) to the bottom of the stack, effectively moving the new space up into the frame.

NOTE The register save area is reserved and should not be used for purposes outside of this document. G

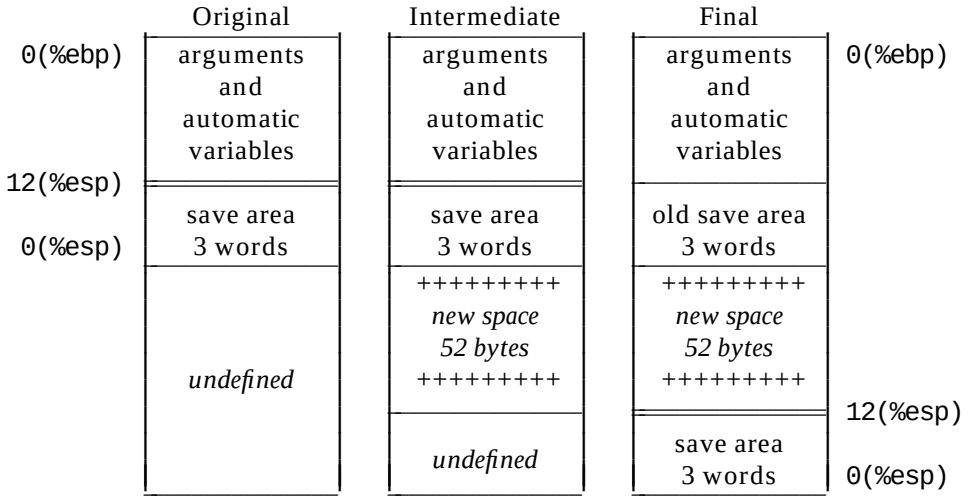

Even in the presence of signals, dynamic allocation is ''safe.'' If a signal interrupts allocation, one of three things can happen.

- The signal handler can return. The process then resumes the dynamic allocation from the point of interruption.
- The signal handler can execute a non-local goto, or `longjmp` [see `setjmp`(BA_LIB)]. This resets the process to a new context in a previous stack frame, automatically discarding the dynamic allocation.
- The process can terminate.

Regardless of when the signal arrives during dynamic allocation, the result is a consistent (though possibly dead) process.

To illustrate, assume a program wants to allocate 50 bytes, and it has saved three registers in the bottom of the frame. The first step is rounding 50 to 52, making it a multiple of 4. Figure 3-49 shows how the stack frame changes.

Figure 3-49: Dynamic Stack Allocation

New space starts at `12(%esp)`. As described, every dynamic allocation in *this* function will return a new area starting at `12(%esp)`, leaving previous heap objects untouched (other functions could have different heap addresses).

Consequently, the compiler should compute the absolute address for each area, avoiding relative references. Otherwise, future allocations in the same frame would destroy the heap's integrity.

Existing stack objects reside at fixed offsets from the frame pointer (%ebp). Dynamic allocation preserves those offsets, because the frame pointer does not change and the objects relative to it do not move. Objects relative to the stack pointer (%esp) move, but their %esp-relative positions do not change. Accordingly, compilers arrange not to publicize the absolute address of any object in the bottom half of the stack frame (in a way that violates the scope rules). %esp-relative references stay valid after dynamic allocation, but absolute addresses do not.

No special code is needed to free dynamically allocated stack memory. The function return resets the stack pointer and removes the entire stack frame, including the heap, from the stack. Naturally, a program should not reference heap objects after they have gone out of scope.

Relocation 4-4
Relocation Types 4-4

ELF Header

Machine Information

For file identification in e_ident, the Intel386 architecture requires the following values.

Figure 4-1: Intel386 Identification, e_ident

Position	Value
e_ident[EI_CLASS]	ELFCLASS32
e_ident[EI_DATA]	ELFDATA2LSB

Processor identification resides in the ELF header's e_machine member and must have the value EM_386.

The ELF header's e_flags member holds bit flags associated with the file. The Intel386 architecture defines no flags; so this member contains zero.

Sections

Special Sections

Various sections hold program and control information. Sections in the list below are used by the system and have the indicated types and attributes.

Figure 4-2: Special Sections

Name	Type	Attributes
.got	SHT_PROGBITS	SHF_ALLOC+SHF_WRITE
.plt	SHT_PROGBITS	SHF_ALLOC+SHF_EXECINSTR

`.got` This section holds the global offset table. See ''Coding Examples'' in Chapter 3 and ''Global Offset Table'' in Chapter 5 for more information.

`.plt` This section holds the procedure linkage table. See ''Procedure Linkage Table'' in Chapter 5 for more information.

Symbol Table

Symbol Values

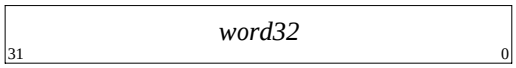

If an executable file contains a reference to a function defined in one of its associated shared objects, the symbol table section for that file will contain an entry for that symbol. The `st_shndx` member of that symbol table entry contains `SHN_UNDEF`. This signals to the dynamic linker that the symbol definition for that function is not contained in the executable file itself. If that symbol has been allocated a procedure linkage table entry in the executable file, and the `st_value` member for that symbol table entry is non-zero, the value will contain the virtual address of the first instruction of that procedure linkage table entry. Otherwise, the `st_value` member contains zero. This procedure linkage table entry address is used by the dynamic linker in resolving references to the address of the function. See ''Function Addresses'' in Chapter 5 for details.

Relocation

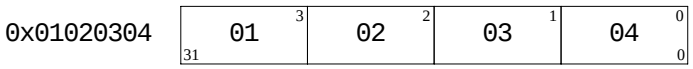

Relocation Types

Relocation entries describe how to alter the following instruction and data fields (bit numbers appear in the lower box corners).

Figure 4-3: Relocatable Fields

word32 This specifies a 32-bit field occupying 4 bytes with arbitrary byte alignment. These values use the same byte order as other word values in the Intel386 architecture.

Calculations below assume the actions are transforming a relocatable file into either an executable or a shared object file. Conceptually, the link editor merges one or more relocatable files to form the output. It first decides how to combine and locate the input files, then updates the symbol values, and finally performs the relocation. Relocations applied to executable or shared object files are similar and accomplish the same result. Descriptions below use the following notation.

A This means the addend used to compute the value of the relocatable field.

B This means the base address at which a shared object has been loaded into memory during execution. Generally, a shared object file is built with a 0 base virtual address, but the execution address will be different. See ''Program Header'' in the System V ABI for more information about the base address.

G This means the offset into the global offset table at which the address of the relocation entry's symbol will reside during execution. See ''Coding Examples'' in Chapter 3 and ''Global Offset Table'' in Chapter 5 for more information.

GOT This means the address of the global offset table. See ''Coding Examples'' in Chapter 3 and ''Global Offset Table'' in Chapter 5 for more information.

L This means the place (section offset or address) of the procedure linkage table entry for a symbol. A procedure linkage table entry redirects a function call to the proper destination. The link editor builds the initial procedure linkage table, and the dynamic linker modifies the entries during execution. See ''Procedure Linkage Table'' in Chapter 5 for more information.

P This means the place (section offset or address) of the storage unit being relocated (computed using `r_offset`).

S This means the value of the symbol whose index resides in the relocation entry.

A relocation entry's `r_offset` value designates the offset or virtual address of the first byte of the affected storage unit. The relocation type specifies which bits to change and how to calculate their values. The Intel386 architecture uses only `Elf32_Rel` relocation entries, the field to be relocated holds the addend. In all cases, the addend and the computed result use the same byte order.

Figure 4-4: Relocation Types

Name	Value	Field	Calculation
R_386_NONE	0	none	none
R_386_32	1	*word32*	S + A
R_386_PC32	2	*word32*	S + A - P
R_386_GOT32	3	*word32*	G + A - P
R_386_PLT32	4	*word32*	L + A - P
R_386_COPY	5	none	none
R_386_GLOB_DAT	6	*word32*	S
R_386_JMP_SLOT	7	*word32*	S
R_386_RELATIVE	8	*word32*	B + A
R_386_GOTOFF	9	*word32*	S + A - GOT
R_386_GOTPC	10	*word32*	GOT + A - P

Some relocation types have semantics beyond simple calculation.

R_386_GOT32 This relocation type computes the distance from the base of the global offset table to the symbol's global offset table entry. It additionally instructs the link editor to build a global offset table.

R_386_PLT32 This relocation type computes the address of the symbol's procedure linkage table entry and additionally instructs the link editor to build a procedure linkage table.

R_386_COPY The link editor creates this relocation type for dynamic linking. Its offset member refers to a location in a writable segment. The symbol table index specifies a symbol that should exist both in the current object file and in a shared object. During execution, the dynamic linker copies data associated with the shared object's symbol to the location specified by the offset.

R_386_GLOB_DAT This relocation type is used to set a global offset table entry to the address of the specified symbol. The special relocation type allows one to determine the correspondence between symbols and global offset table entries.

R_386_JMP_SLOT The link editor creates this relocation type for dynamic linking. Its offset member gives the location of a procedure linkage table entry. The dynamic linker modifies the procedure linkage table entry to transfer control to the designated symbol's address [see ''Procedure Linkage Table'' in Chapter 5].

R_386_RELATIVE The link editor creates this relocation type for dynamic linking. Its offset member gives a location within a shared object that contains a value representing a relative address. The dynamic linker computes the corresponding virtual address by adding the virtual address at which the shared object was loaded to the relative address. Relocation entries for this type must specify 0 for the symbol table index.

R_386_GOTOFF This relocation type computes the difference between a symbol's value and the address of the global offset table. It additionally instructs the link editor to build the global offset table.

R_386_GOTPC This relocation type resembles R_386_PC32, except it uses the address of the global offset table in its calculation. The symbol referenced in this relocation normally is _GLOBAL_OFFSET_TABLE_, which additionally instructs the link editor to build the global offset table.

Program Loading

As the system creates or augments a process image, it logically copies a file's segment to a virtual memory segment. When—and if—the system physically reads the file depends on the program's execution behavior, system load, and so on. A process does not require a physical page unless it references the logical page during execution, and processes commonly leave many pages unreferenced. Therefore delaying physical reads frequently obviates them, improving system performance. To obtain this efficiency in practice, executable and shared object files must have segment images whose file offsets and virtual addresses are congruent, modulo the page size.

Virtual addresses and file offsets for the Intel386 architecture segments are congruent modulo 4 KB (`0x1000`) or larger powers of 2. Because 4 KB is the maximum page size, the files will be suitable for paging regardless of physical page size.

Figure 5-1: Executable File

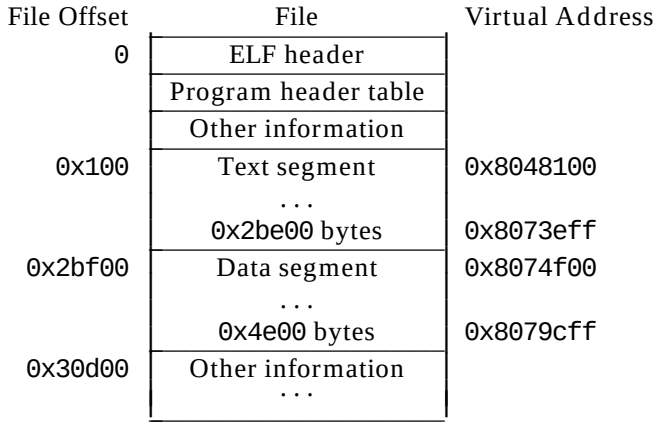

Figure 5-2: Program Header Segments

Member	Text	Data
p_type	PT_LOAD	PT_LOAD
p_offset	0x100	0x2bf00
p_vaddr	0x8048100	0x8074f00
p_paddr	unspecified	unspecified
p_filesz	0x2be00	0x4e00
p_memsz	0x2be00	0x5e24
p_flags	PF_R+PF_X	PF_R+PF_W+PF_X
p_align	0x1000	0x1000

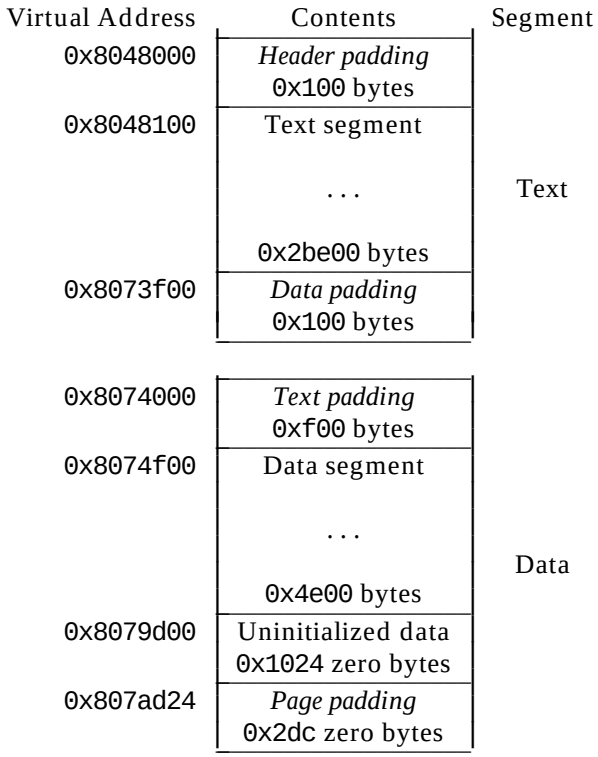

Although the example's file offsets and virtual addresses are congruent modulo 4 KB for both text and data, up to four file pages hold impure text or data (depending on page size and file system block size).

- The first text page contains the ELF header, the program header table, and other information.
- The last text page holds a copy of the beginning of data.
- The first data page has a copy of the end of text.
- The last data page may contain file information not relevant to the running process.

Logically, the system enforces the memory permissions as if each segment were complete and separate; segments' addresses are adjusted to ensure each logical page in the address space has a single set of permissions. In the example above, the region of the file holding the end of text and the beginning of data will be mapped twice: at one virtual address for text and at a different virtual address for data.

The end of the data segment requires special handling for uninitialized data, which the system defines to begin with zero values. Thus if a file's last data page includes information not in the logical memory page, the extraneous data must be set to zero, not the unknown contents of the executable file. ''Impurities'' in the other three pages are not logically part of the process image; whether the system expunges them is unspecified. The memory image for this program follows, assuming 4 KB (0x1000) pages.

Figure 5-3: Process Image Segments

One aspect of segment loading differs between executable files and shared objects. Executable file segments typically contain absolute code (see ''Coding Examples'' in Chapter 3). To let the process execute correctly, the segments must reside at the virtual addresses used to build the executable file. Thus the system uses the `p_vaddr` values unchanged as virtual addresses.

On the other hand, shared object segments typically contain position-independent code. This lets a segment's virtual address change from one process to another, without invalidating execution behavior. Though the system chooses virtual addresses for individual processes, it maintains the segments' *relative positions*. Because position-independent code uses relative addressing between segments, the difference between virtual addresses in memory must match the difference between virtual addresses in the file. The following table shows possible shared object virtual address assignments for several processes, illustrating constant relative positioning. The table also illustrates the base address computations.

Figure 5-4: Example Shared Object Segment Addresses

Source	Text	Data	Base Address
File	0x200	0x2a400	0x0
Process 1	0x80000200	0x8002a400	0x80000000
Process 2	0x80081200	0x800ab400	0x80081000
Process 3	0x900c0200	0x900ea400	0x900c0000
Process 4	0x900c6200	0x900f0400	0x900c6000

Dynamic Linking

Dynamic Section

Dynamic section entries give information to the dynamic linker. Some of this information is processor-specific, including the interpretation of some entries in the dynamic structure.

DT_PLTGOT — On the Intel386 architecture, this entry's d_ptr member gives the address of the first entry in the global offset table. As mentioned below, the first three global offset table entries are reserved, and two are used to hold procedure linkage table information.

Global Offset Table

Position-independent code cannot, in general, contain absolute virtual addresses. Global offset tables hold absolute addresses in private data, thus making the addresses available without compromising the position-independence and sharability of a program's text. A program references its global offset table using position-independent addressing and extracts absolute values, thus redirecting position-independent references to absolute locations.

Initially, the global offset table holds information as required by its relocation entries [see ''Relocation'' in Chapter 4]. After the system creates memory segments for a loadable object file, the dynamic linker processes the relocation entries, some of which will be type R_386_GLOB_DAT referring to the global offset table. The dynamic linker determines the associated symbol values, calculates their absolute addresses, and sets the appropriate memory table entries to the proper values. Although the absolute addresses are unknown when the link editor builds an object file, the dynamic linker knows the addresses of all memory segments and can thus calculate the absolute addresses of the symbols contained therein.

If a program requires direct access to the absolute address of a symbol, that symbol will have a global offset table entry. Because the executable file and shared objects have separate global offset tables, a symbol's address may appear in several tables. The dynamic linker processes all the global offset table relocations before giving control to any code in the process image, thus ensuring the absolute addresses are available during execution.

The table's entry zero is reserved to hold the address of the dynamic structure, referenced with the symbol _DYNAMIC. This allows a program, such as the dynamic linker, to find its own dynamic structure without having yet processed its relocation entries. This is especially important for the dynamic linker, because it must initialize itself without relying on other programs to relocate its memory image. On the Intel386 architecture, entries one and two in the global offset table also are reserved. ''Procedure Linkage Table'' below describes them.

The system may choose different memory segment addresses for the same shared object in different programs; it may even choose different library addresses for different executions of the same program. Nonetheless, memory segments do not change addresses once the process image is established. As long as a process exists, its memory segments reside at fixed virtual addresses.

A global offset table's format and interpretation are processor-specific. For the Intel386 architecture, the symbol _GLOBAL_OFFSET_TABLE_ may be used to access the table.

Figure 5-5: Global Offset Table

```
extern Elf32_Addr   _GLOBAL_OFFSET_TABLE_[];
```

The symbol _GLOBAL_OFFSET_TABLE_ may reside in the middle of the .got section, allowing both negative and non-negative ''subscripts'' into the array of addresses.

Function Addresses

References to the address of a function from an executable file and the shared objects associated with it might not resolve to the same value. References from within shared objects will normally be resolved by the dynamic linker to the virtual address of the function itself. References from within the executable file to a function defined in a shared object will normally be resolved by the link editor to the address of the procedure linkage table entry for that function within the executable file.

To allow comparisons of function addresses to work as expected, if an executable file references a function defined in a shared object, the link editor will place the address of the procedure linkage table entry for that function in its associated symbol table entry. [See ''Symbol Values'' in Chapter 4]. The dynamic linker

treats such symbol table entries specially. If the dynamic linker is searching for a symbol, and encounters a symbol table entry for that symbol in the executable file, it normally follows the rules below.

1. If the `st_shndx` member of the symbol table entry is not `SHN_UNDEF`, the dynamic linker has found a definition for the symbol and uses its `st_value` member as the symbol's address.
2. If the `st_shndx` member is `SHN_UNDEF` and the symbol is of type `STT_FUNC` and the `st_value` member is not zero, the dynamic linker recognizes this entry as special and uses the `st_value` member as the symbol's address.
3. Otherwise, the dynamic linker considers the symbol to be undefined within the executable file and continues processing.

Some relocations are associated with procedure linkage table entries. These entries are used for direct function calls rather than for references to function addresses. These relocations are not treated in the special way described above because the dynamic linker must not redirect procedure linkage table entries to point to themselves.

Procedure Linkage Table

Much as the global offset table redirects position-independent address calculations to absolute locations, the procedure linkage table redirects position-independent function calls to absolute locations. The link editor cannot resolve execution transfers (such as function calls) from one executable or shared object to another. Consequently, the link editor arranges to have the program transfer control to entries in the procedure linkage table. On the Intel386 architecture, procedure linkage tables reside in shared text, but they use addresses in the private global offset table. The dynamic linker determines the destinations' absolute addresses and modifies the global offset table's memory image accordingly. The dynamic linker thus can redirect the entries without compromising the position-independence and sharability of the program's text. Executable files and shared object files have separate procedure linkage tables.

Figure 5-6: Absolute Procedure Linkage Table

```
.PLT0: pushl  got_plus_4
       jmp    *got_plus_8
       nop; nop
       nop; nop
.PLT1: jmp    *name1_in_GOT
       pushl  $offset
       jmp    .PLT0@PC
.PLT2: jmp    *name2_in_GOT
       pushl  $offset
       jmp    .PLT0@PC
       ...
```

Figure 5-7: Position-Independent Procedure Linkage Table

```
.PLT0: pushl  4(%ebx)
       jmp    *8(%ebx)
       nop; nop
       nop; nop
.PLT1: jmp    *name1@GOT(%ebx)
       pushl  $offset
       jmp    .PLT0@PC
.PLT2: jmp    *name2@GOT(%ebx)
       pushl  $offset
       jmp    .PLT0@PC
       ...
```

NOTE As the figures show, the procedure linkage table instructions use different operand addressing modes for absolute code and for position-independent code. Nonetheless, their interfaces to the dynamic linker are the same.

Following the steps below, the dynamic linker and the program ''cooperate'' to resolve symbolic references through the procedure linkage table and the global offset table.

1. When first creating the memory image of the program, the dynamic linker sets the second and the third entries in the global offset table to special values. Steps below explain more about these values.
2. If the procedure linkage table is position-independent, the address of the global offset table must reside in `%ebx`. Each shared object file in the process image has its own procedure linkage table, and control transfers to a procedure linkage table entry only from within the same object file. Consequently, the calling function is responsible for setting the global offset table base register before calling the procedure linkage table entry.
3. For illustration, assume the program calls `name1`, which transfers control to the label `.PLT1`.
4. The first instruction jumps to the address in the global offset table entry for `name1`. Initially, the global offset table holds the address of the following `pushl` instruction, not the real address of `name1`.
5. Consequently, the program pushes a relocation offset (*offset*) on the stack. The relocation offset is a 32-bit, non-negative byte offset into the relocation table. The designated relocation entry will have type `R_386_JMP_SLOT`, and its offset will specify the global offset table entry used in the previous `jmp` instruction. The relocation entry also contains a symbol table index, thus telling the dynamic linker what symbol is being referenced, `name1` in this case.
6. After pushing the relocation offset, the program then jumps to `.PLT0`, the first entry in the procedure linkage table. The `pushl` instruction places the value of the second global offset table entry (*got_plus_4* or `4(%ebx)`) on the stack, thus giving the dynamic linker one word of identifying information. The program then jumps to the address in the third global offset table entry (*got_plus_8* or `8(%ebx)`), which transfers control to the dynamic linker.
7. When the dynamic linker receives control, it unwinds the stack, looks at the designated relocation entry, finds the symbol's value, stores the ''real'' address for `name1` in its global offset table entry, and transfers control to the desired destination.

8. Subsequent executions of the procedure linkage table entry will transfer directly to `name1`, without calling the dynamic linker a second time. That is, the `jmp` instruction at `.PLT1` will transfer to `name1`, instead of ''falling through'' to the `pushl` instruction.

The `LD_BIND_NOW` environment variable can change dynamic linking behavior. If its value is non-null, the dynamic linker evaluates procedure linkage table entries before transferring control to the program. That is, the dynamic linker processes relocation entries of type `R_386_JMP_SLOT` during process initialization. Otherwise, the dynamic linker evaluates procedure linkage table entries lazily, delaying symbol resolution and relocation until the first execution of a table entry.

NOTE

Lazy binding generally improves overall application performance, because unused symbols do not incur the dynamic linking overhead. Nevertheless, two situations make lazy binding undesirable for some applications. First, the initial reference to a shared object function takes longer than subsequent calls, because the dynamic linker intercepts the call to resolve the symbol. Some applications cannot tolerate this unpredictability. Second, if an error occurs and the dynamic linker cannot resolve the symbol, the dynamic linker will terminate the program. Under lazy binding, this might occur at arbitrary times. Once again, some applications cannot tolerate this unpredictability. By turning off lazy binding, the dynamic linker forces the failure to occur during process initialization, before the application receives control.

Program Interpreter G

There is one valid program interpreter for programs conforming to the Intel386 ABI: G

```
/usr/lib/libc.so.1                                    G
```

C Library M

Additional Entry Points

The following routines are included in the **libc** library to provide entry points for the required source-level interface listed in the *System V ABI*. A description and syntax symmary for each function follows the table. M

Figure 6-2: `libc` **Additional Required Entry Points**

`_fxstat _lxstat _xmknod _xstat nuname _nuname`

`int _fxstat(int, int, struct stat *);`
: The semantics of this function are identical to those of the `fstat`(BA_OS) function described in the *System V Interface Definition, Edition 4*. Its only difference is that it requires an extra first argument whose value must be 2.

`int _lxstat(int, char *, struct stat *);`
: The semantics of this function are identical to those of the `lstat`(BA_OS) function described in the *System V Interface Definition, Edition 4*. Its only difference is that it requires an extra first argument whose value must be 2.

`int nuname(struct utsname *);`
: The semantics and syntax of this function are identical to those of the `uname`(BA_OS) function described in the *System V Interface Definition, Edition 4*. The symbol `_nuname` is also available with the same semantics.

`int _xmknod(int, char *, mode_t, dev_t);`
: The semantics of this function are identical to those of the `mknod`(BA_OS) function described in the *System V Interface Definition, Edition 4*. Its only difference is that it requires an extra first argument whose value must be 2.

`int _xstat(int, char *, struct stat *);`
: The semantics of this function are identical to those of the `stat`(BA_OS) function described in the *System V Interface*

Definition, Edition 4. Its only difference is that it requires an extra first argument whose value must be 2.

Support Routines

Besides operating system services, **libc** contains the following processor-specific support routines. M

Figure 6-3: `libc`**, Support Routines**

`_fpstart`	`_ _fpstart`	`sbrk`	`_sbrk`

`char *sbrk(int incr);`

This function adds *incr* bytes to the *break value* and changes the allocated space accordingly. *Incr* can be negative, in which case the amount of allocated space is decreased. The break value is the address of the first allocation beyond the end of the data segment. The amount of allocated space increases as the break value increases. Newly allocated space is set to zero. If, however, the same memory space is reallocated to the same process, its contents are undefined. Upon successful completion, `sbrk` returns the old break value. Otherwise, it returns `-1` and sets `errno` to indicate the error. The symbol `_sbrk` is also available with the same semantics.

`void __fpstart(void);`

This function calls `_fpstart()`, to initialize the floating-point environment.

`void _fpstart(void);`

This function initializes the floating-point execution environment. It sets _fp_hw to the appropriate value. It sets the rounding mode to ‘‘nearest.’’ It also resets the Intel387 control word to the default state.

Global Data Symbols

The libc library requires that some globel external data objects be defined for the routines to work properly. In addition to the corresponding data symbols listed in the *System V ABI*, the following symbols must be provided in the system library on all ABI-conforming systems implemented with the Intel386 architecture. Declarations for the data objects listed below can be found in the Data Definitions section of this chapter or immediately following the table. M

Figure 6-4: libc, Global External Data Symbols

__flt_rounds	_fp_hw	__huge_val

```
extern int _fp_hw;
```

This variable describes the floating-point hardware available. If the value is zero, no floating-point support is present. If the value is 1, the floating-point support is provided by an Intel387 software emulator. If the value is 2, an 80287 chip is available. If the value is 3, an Intel387 chip is available. System software sets the value appropriately, before transferring control to main.

Application Constraints

As described above, libc provides symbols for applications. In a few cases, however, an application is obliged to provide symbols for the library. In addition to the application-provided symbols listed in this section of the *System V ABI*, conforming applications on the Intel386 architecture are also required to provide the following symbols. M

```
extern _end;
```

This symbol refers neither to a routine nor to a location with interesting contents. Instead, its address must correspond to the beginning of a program's dynamic allocation area, called the heap. Typically, the heap begins immediately after the data segment of the program's executable file.

```
extern const int _lib_version;
```

This variable's value specifies the compilation and execution mode for the program. If the value is zero, the program wants to preserve the semantics of older (pre-ANSI) C, where conflicts exist with ANSI. Otherwise, the value is non-zero, and the program wants ANSI C semantics.

System Data Interfaces

Data Definitions

This section contains standard data definitions that describe system data. These files are referred to by their names in angle brackets: <*name.h*> and <sys/*name.h*>. Included in these data definitions are macro definitions and data definitions.

The data objects described in this section are part of the interface between an ABI-conforming application and the underlying ABI-conforming system where it will run. While an ABI-conforming system must provide these interfaces, it is not required to contain the actual data definitions referenced here. Programmers should observe that the sources of the structures defined in these data definitions are defined in SVID.

ANSI C serves as the ABI reference programming language, and data definitions are specificed in ANSI C format. The C language is used here as a convenient notation. Using a C language description of these data objects does *not* preclude their use by other programming languages. M

Reentrancy Considerations M

New conventions have been added to accomodate the new requirements of reen- M
trancy. Some historic binary code sequences are inherently non-reentrant. Unless M
great care is taken, multi-threaded applications cannot safely use such sequences. M
The most portable (i.e. those guaranteed to work in all cases) are those that are M
marked as reentrant in this chapter. For the ABI, this sometimes requires that two M
definitions exist for these interfaces, one that is reentrant and one that is not. M
These are indicated by comments that define which of the alternate definitions is M
reentrant. These alternatives are not selected at run-time, but are intended to be M
bound at application build time.

NOTE All information presented in the figures marked with * are new to the Fourth Edition of the psABI. M

Figure 6-5: <aio.h>*

```

CAUTION

The data definitions in ctype.h are moved to Level 2 as of January 1, 1993. In order to correctly function in an internationalized environment, applications are encouraged to use the functions in libc instead. M

```

† These macro definitions are moved to Level 2 as of January 1, 1993.

†† The `_file` member of the `FILE` struct is moved to Level 2 as of January 1, 1993.

NOTE

The macros `clearerr`, and `fileno` will be removed as a source interface in a future release supporting multi-processing. Applications should transition to the function equivalents of these macros in libc. Binary portability will be supported for existing applications.

CAUTION

The constant `_NFILE` has been removed. It should still appear in stdio.h, but may be removed in a future version of the header file. Applications may not be able to depend on `fopen()` failing on an attempt to open more than `_NFILE` files.

```

NOTE

This edition introduces the xti.h header which contains the same information as the current tiuser.h. The new xti.h header is a superset of the previous edition's tiuser.h. M M M

tiuser.h has been moved to Level 2 and will be removed in future editions of the ABI. In the future xti.h should be used as a replacement for tiuser.h.

NOTE

The construction inline is a syntactic extension to ANSI C and may not be supported by all C compilers. The intended semantics are to behave like regular preprocessor function like macros except parameter names are local and expressions giving their initial values are evaluated exactly once. M M

X Window Data Definitions

NOTE

This section is new to the Third Edition of this document, but will not be marked with the "G" diff-mark.

This section contains standard data definitions that describe system data for the optional X Window System libraries listed in the Generic ABI. These data definitions are referred to by their names in angle brackets: <*name.h*> and <sys/*name.h*>. Included in these data definitions are macro definitions and structure definitions. While an ABI-conforming system may provide X11 and X Toolkit Intrinsics interfaces, it need not contain the actual data definitions referenced here. Programmers should observe that the sources of the structures defined in these data definitions are defined in SVID or the appropriate X Consortium documentation (see chapter 10 in the Generic ABI).

Motif 1.2 Data Definitions

This section contains standard data definitions that describe system data for the optional Motif 1.2 libraries. These data definitions are referred to by their names in angle brackets: <*name.h*> and <sys/*name.h*>. Included in these data definitions are macro definitions and structure definitions. While an ABI-conforming system may provide Motif 1.2 interfaces, it need not contain the actual data definitions referenced here. Programmers should observe that the sources of the structures defined in these data definitions are defined in SVID or the appropriate Motif documentation (see chapter 10 in the Generic ABI).

TCP/IP Data Definitions

NOTE

This section is new to the Third Edition of this document, but will not be marked with the "G" diff-mark.

This section contains standard data definitions that describe system data for the optional TCP / IP Interfaces. These data definitions are referred to by their names in angle brackets: <*name.h*> and <sys / *name.h*>. Included in these data definitions are macro definitions and structure definitions. While an ABI-conforming system may provide TCP / IP interfaces, it need not contain the actual data definitions referenced here. Programmers should observe that the sources of the structures defined in these data definitions are defined in SVID.

Figure 6-322: <netinet/in.h>

```
#define      IPPROTO_IP   0
#define      IPPROTO_TCP  6

struct in_addr {
       union {
              struct { u_char s_b1,s_b2,s_b3,s_b4; } S_un_b;
              struct { u_short s_w1,s_w2; } S_un_w;
              u_long S_addr;
       } S_un;
#define      s_addr       S_un.S_addr
};

#define      INADDR_ANY               (u_long)0x00000000
#define      INADDR_LOOPBACK          (u_long)0x7F000001
#define      INADDR_BROADCAST         (u_long)0xffffffff

#define      IN_SET_LOOPBACK_ADDR(a) \
       {(a)->sin_addr.s_addr = htonl(INADDR_LOOPBACK); \
       (a)->sin_family = AF_INET;}

struct sockaddr_in {
       short        sin_family;
       u_short      sin_port;
       struct in_addr      sin_addr;
       char         sin_zero[8];
};

#define      IP_OPTIONS   1
```

7 DEVELOPMENT ENVIRONMENT

Development Commands 7-1
PATH Access to Development Tools 7-1

Software Packaging Tools 7-2
System Headers 7-2
Static Archives 7-2

Development Commands

NOTE THE FACILITIES AND INTERFACES DESCRIBED IN THIS SECTION ARE OPTIONAL COMPONENTS OF THE *System V Application Binary Interface*.

NOTE *This section is new to the Third Edition of this document, but will not be marked with the "G" diff-mark.*

The Development Environment for Intel386 implementations of UnixWare® 2.0 will contain all of the development commands required by the System V ABI, namely; M

as	cc	ld
m4	lex	yacc

Each command accepts all of the options required by the System V ABI, as defined in the SD_CMD section of the *System V Interface Definition, Edition 4*.

PATH Access to Development Tools

The development environment for the Intel386 System V implementations is accessible using the system default value for PATH. The default if no options are given to the cc command is to use the libraries and object file formats that are required for ABI compliance.

Software Packaging Tools

The development environment for i386 implementations of the System V ABI shall include each of the following commands as defined in the AS_CMD section of - *System V Interface Definition, Edition 4*.

`pkgproto` `pkgtrans` `pkgmk`

System Headers

Systems that do not have an ABI Development Environment may not have system header files. If an ABI Development Environment is supported, system header files will be included with the Development Environment. The primary source for contents of header files is always the *System V Interface Definition, Edition 4*. In those cases where SVID Fourth Edition doesn't specify the contents of system headers, Chapter 6 "Data Definitions" of this document shall define the associations of data elements to system headers for compilation. For greatest source portability, applications should only depend on header file contents defined in SVID.

Static Archives

Level 1 interfaces defined in *System V Interface Definition, Edition 4*, for each of the following libraries, may be statically linked safely into applications. The resulting executable will not be made non-compliant to the ABI solely because of the static linkage of such members in the executable.

`libcurses` `libm`

The archive `libcurses.a` is located in /usr/lib on conforming i386 development environments. The archive `libm.a` is located in /usr/lib on conforming i386 development environments. M

8 EXECUTION ENVIRONMENT

Application Environment 8-1
The /dev Subtree 8-1

Application Environment

NOTE

This section is new to the Third Edition of this document, but will not be marked with the "G" diff-mark.

This section specifies the execution environment information available to application programs running on an i386 ABI-conforming computer.

The /dev Subtree

All networking device files described in the Generic ABI shall be supported on all i386 ABI-conforming computers. In addition, the following device files are required to be present on all i386 ABI-conforming computers.

`/dev/null` This device file is a special ‘‘null’’ device that may be used to test programs or provide a data sink. This file is writable by all processes.

`/dev/tty` This device file is a special one that directs all output to the controlling TTY of the current process group. This file is readable and writable by all processes.

`/dev/sxtXX`
`/dev/ttyXX` These device files, where XX represents a two-digit integer, represent device entries for terminal sessions. All these device files must be examined by the `ttyname()` call. Applications must not have the device names of individual terminals hard-coded within them. The `sxt` entries are optional in the system but, if present must be included in the library routine’s search.

The following device files are required to be present on all i386 ABI-conforming computers that support the corresponding hardware devices.

`/dev/lpX` This device file is the lineprinter device. The letter ‘‘X’’ represents a one-digit integer that identifies the particular lineprinter device.

`/dev/dsk/`
`/dev/rdsk/` These directories contain the raw and block disk device files. They are of the form:

```
f[01][t]
f[01][35][dh][t]
c#t#d#s#
```

where ’c’ is followed by a controller number,
’t’ is followed by a target number,
’d’ is followed by a disk unit number,
’s’ is followed by a disk slice number.

`/dev/rmt/` These directories contain the raw and block tape device files. The devices guaranteed to be in this directory are:

```
ctape1
ntape1
```

`/dev/cdrom/`
`/dev/rcdrom/` These directories contain the raw and block CD-ROM disk device files. They are of the form:

```
c#t#l#
c#t#l#
cdrom#
```

The letter ’c’ is followed by a controller number. The letter ’t’ is followed by a target number on the controller. The letter ’l’ is followed by a logical unit number on the target. The device "cdrom" is followed by a sequential number as nodes are created.

No leading zeroes are used in the numbers (target four is t4 not t04). The numbering for ’c’, ’t’ and ’l’ begins at zero and the numbering for ’n’ begins at one.
